INDEX

NAME INDEX

, A. J. : Awarded a Postgraduate Agricultural Scholarship by the
istry of Agriculture and Fisheries, 683
. R., and Miller, S. A. : Observation of Cool Flames with Ethylene,
4
ble, K. C. : Awarded a Postgraduate Agricultural Scholarship
the Ministry of Agriculture and Fisheries, 683
ble, Michael (edited by Johnson, M. L., and) : New Biology, No.
, 1032
Mark : Social Surveys and Social Action, *review* by Prof. T. H.
rshall, 847
V. : Awarded an extra Mather Premium of the Institution of
ectrical Engineers, 103
, R. D. : Development of Electric Lighting, 238
l Society of America : Autumn Technical Meeting, 411
R. : Some Aspects of Discharge Physics, 142
ciety Trust : Nationalized Industry Series 4, The Men on the Boards,
Study of the Composition of Boards of Nationalized Industry, 130
onalized Industry Series 6 and 7, The Extent of Centralization, 982
onalized Industry Series 8, The Future of the Unions, 1094
rother : Thixotropic Breakdown and other Rheological Properties
Honey, 945
P. : Appointed staff surveyor, Kenya, 276
, D. W., and others : Geometrical Isomers in a Series of Anti-
stamines, 204
, J. : Ocular Scanning and Depth Perception, 345
, Lord : *Death* of, 1065
B. : Awarded a Kelvin Premium of the Institution of Electrical
ngineers, 103
Prof. E. D. : Honorary degree of LL.D. of the University of Glasgow
onferred on, 155
iversary Address to the Royal Society, 1017
ted president of the Royal Society for 1952, 1066
search, Ltd. : Summer School on the Technology of Synthetic
esin Adhesives, 236
tical Society, Royal : Wilbur Wright Memorial Lecture (A. E.
aymond), 276
ish Commonwealth and Empire Lecture (Air Vice-Marshal Sir E. M.
tt), 276
rds of Medals and Prizes, 498
East) Medical Survey : Annual Report for 1950, 898
(East) Agriculture and Forestry Research Organization (Dr. B. A.
Keen), 674
(East) Industrial Research Board : Eighth Annual Report, 235
. W., and Revell, R. S. M. : Technique of Electron Microscopy, 819
rof. W. E. : *Death* of, 100 ; *obituary* by Sir John Graham Kerr, 494
ural Research Council : Commonwealth Potato Collection trans-
rred to the control of the, and to be known in future as the Potato
enetics Station, 681
ppointment of Sir Alan Drury as a member for a further term, 683
ointment of Prof. S. J. Watson as a member, 683
Survey Research Board Report No. 3 (1950), 1105
re for Scotland, Department of : Postgraduate Agricultural
cholarship Awards, 589
ure and Fisheries, Ministry of : Postgraduate Agricultural Scholar-
p Awards, 683
. A. (Champion, Dr. F. C., and) : Existence and Nature of the
ctive Particles' near a Source of Radium E, 780
of. A. C. : Honorary degree of LL.D. of the University of Glasgow
ferred on, 155
. R. G. : *Obituary* by Sir Harold Spencer Jones, 936
Prof. Hideo, and others : Electrical Conductivity and Magnetic
eptibility of Ovalene, 520
y, J., and others : Chlorophyll Inhibition and Growth Regulation
everal Tetronic Acid Derivatives, 85
of. Adrien : The Acridines, *review* by Dr. J. Walker, 713
B., and Richardson, Dr. F. D. : Thermodynamics of Ferrous
phide, 661
Dr. J. N. : Changes in Colour Sensitivity of the Eye with Posture,
Dr. P. : A Resistant Membrane in Wool, 1081
. T., et [illegible], Prof. R. B. (Mark, Prof. H., avec la collabora-
de) : État actuel de la chimie et de la physique des molécules
es, *review* by Dr. D. P. Riley, 355
. H. : The Impossibility of Determining the Sun's General
etic Field by Zeeman Effect Measurements, 1036
J. : Chemotherapy of Tuberculosis, 540
Norma (Astrup, Dr. Tage, and) : Quaternary Detergents and
ctivity of Trypsin and Plasmin, 565
ouglas A. : The Scottish Scene, 233
ion of Knight of the Order of the Dannebrog bestowed on, by
the King of Denmark, 641
: Appointed assistant conservator of forests, Fiji, 983
Clifford : Inferiority Feelings in the Individual and the Group,
w, 972
C. W. : Appointed to the Perren chair of astronomy at Univer-
College, London, 500, 1025 ; work of, 1025
Appointed a senior agricultural officer, Federation of Malaya,
. Fred H., and others : Inheritance of the Human Blood
Antigen Jka, 207
., and others : Mechanical Properties of α-Solid Solutions of
, with Zinc, Gallium, Germanium and Arsenic, 378

Allen, Miss R. E. A. : Chemistry and Bacteriology of Silage, 731
Allen, W. D. : Separation of Stable Isotopes by Electromagnetic Means, 451
Allison, D : Radiochemical Techniques in Analysis, 154
Allmand, Prof. A. J. : *Death* of, 236 ; *obituary* by Prof. G. Temple, 408
Allsopp, A. : *Marsilea* spp.—Materials for the Experimental Study of Morphogenesis, 301
Altman, Kurt I., and others : Surgically Induced Splenogenic Anaemia in the Rabbit, 827
Amateur Entomologists' Society : Annual Exhibition, 147
Amelinckx, S. : Growth Mechanism of Carborundum Crystals, 431
American Association of Physics Teachers : Presentation of the Oersted Medal to Prof. J. W. Hornbeck, 156
  Tenth Richtmyer Memorial Lecture (Prof. J. C. Slater), 156
  Autumn Technical Meeting, 411
American Chemical Society (Division of Industrial and Engineering Chemistry) : Eighteenth Christmas Chemical Engineering Symposium, 500
American Chemical Society (Pittsburgh Section) : Pittsburgh Award made to Dr. W. A. Gruse, 1104
American Chemical Society and International Chemistry (Sir Eric K. Rideal), 765
American Crystallographic Association : Autumn Technical Meeting, 411
American Institute of Physics : Twentieth Anniversary of the, 411
  Symposium on Physics To-day, 411
American Physical Society : Annual Meeting, 156
  Autumn Technical Meeting, 411
American Society of Civil Engineers (Houston Branch), and others : Second Conference on Coastal Engineering, 456
American Society for the Study of Sterility : Prize for an essay on Infertility and Sterility, 858
Amoroso, Prof. E. C. : Title of professor of veterinary physiology in the University of London conferred on, 18
Amoroso, Prof. E. C., and others : Reproductive Organs of Near-Term and New-Born Seals, 771
Ananthakrishnan, Dr. R. : Intensity Variation in Sunspots, 291
Anderson, —, and others : Underground-Railway Planning and Railway Bridges, 239
Anderson, Dr. David S. : *Obituary* of Prof. A. L. Mellanby, 1064
Anderson, E. B. : Elected an honorary member of the Society of Dairy Technology, 321
Anderson, J. : Appointed a chief scientific officer in the Royal Naval Scientific Service, 1025 ; work of, 1025
Anderson, Dr. J. : Appointed assistant director of veterinary research, Kenya, 147
Anderson, Dr. M. L. : Appointed to the chair of forestry at the University of Edinburgh, 812 ; work of, 812
Anderson, R. A. (Smith, R. D., and) : 31-keV. Excited State of Aluminium-28, 429
Anderson, Robert B., and others : Adsorption of Water and Methanol on Coal, 124
Andrade, Prof. E. N. da C. : Physics from 1850 to 1900, 622
  Presented with the Grande Médaille Osmond by the Société Française de Métallurgie, 768 ; work of, 768
  Formula for Creep Curves of Metals, 1007
Andrewes, Dr. C. H. : Freezing and Drying, 852
Andrews, Prof. J. P. : Appointed vice-president and professor of physics at University College, Ibadan, 17 ; work of, 17
Angerer, Dr. E. v. : Wissenschaftliche Photographie, vierte Auflage, *review* by L. V. Chilton, 485
Angwin, Sir Stanley : Development of Telecommunications, 238
Animal Welfare, Universities' Federation for : Silver Jubilee (Prof. A. N. Worden), 169
Anstey, Dr. E. : Current Trends in Occupational Psychology, 370
Anthony, Colonel H. D. : Humanism and Technology, *review*, 530
Anthropological Institute, Royal : Annual Report, 455
  Grant of £14,000 from the Nuffield Foundation to establish the Nuffield Blood Group Centre, 588
Anti-Locust Research Centre : Report of the Director for 1950–51, 815
Apia Observatory : Annual Report for 1941, 1106
Appleton, Sir Edward : World Communications—The Impact of Speed, 446
Appleyard, H. M. (Auber, L., and) : Surface Cells of Feather Barbs, 736
Arber, Dr. Agnes : *Obituary* of Prof. F. W. Oliver, 809
Archer, D. : Awarded a Postgraduate Agricultural Scholarship by the Ministry of Agriculture and Fisheries, 683
Arley, Prof. Niels, and Buch, Prof. K. Rander : Introduction to the Theory of Probability and Statistics, *review* by David G. Kendall, 217
Armagh Observatory : Report for 1950 (Dr. E. M. Lindsay), 504
Armitage, Dr. J. B., and others : Synthesis of Polyacetylenic Compounds, 900
Armourers and Brasiers' Company (Committee of the Royal Society and the) : Appointment of Dr. A. J. Kennedy as Armourers and Brasiers' Company Research Fellow at the Royal Institution, 189
Armstrong, W. G., and Atkinson, H. F. : Transamination in the Human Tooth, 695
Arndt, Dr. U. W. : Electronic Devices, *review*, 50
  Electronics, *review*, 716
Arnold, Dr. A. H. M. : Awarded a Silvanus Thompson Premium of the Institution of Electrical Engineers, 103
Aronson, M., and others : Histamine Release by Anaphylatoxin, 465
Arts, Royal Society of : R. B. Bennett Empire Prize for 1951 awarded to E. Bruce Levy, 456

NAME INDEX

Asahina, Prof. Yasuhiko, and Shibata, Prof. Shoji : Chemistry of Lichen Substances, *review* by Dr. J. C. Dacre, 889
Ashbridge, Sir Noel : British Television Service, 238
Ashton, E. H., and Zuckerman, Prof. S. : Statistical Methods in Anthropology, 1117
Askew, Major, W. G. (edited by Gullan, Lieut.-Colonel S. C., and) : Metallurgical Abstracts (General and Non-Ferrous), Vol. 16, 1948–49, *review* by Dr W. Hume-Rothery, 1016
Aslakson, Comdr. Carl I. : A New Measurement of the Velocity of Radio Waves, 505
Aslib : To establish an Aeronautical Information Study Group, 276
  Twenty-sixth Annual Conference, 321
  Inauguration of an Aeronautical Engineering Group, 638
  Annual Conference, 682
Asolkar, G. V., and others : A Magnetic Analogue of the Joshi Effect, 1006
Aspinall, P. (Dunsford, I., and) : The *Rh* Chromosome *CwdE* (*Ryw*) occurring in Three Generations, 954
Asquith, R. S. : Paper Chromatography of the Pyrogallol Tannins, 738
Astbury, Prof. N. F. : Appointed to the chair of physics at Gordon Memorial College, Khartoum, 456
Astbury, Prof. W. T. : Elected a corresponding member of the Istituto Lombardo di Scienze e Lettere, 545
Astbury, Prof. W. T., and others : Biophysical Studies of Rheumatoid Connective Tissue, 493
Astronautical Federation, International : Foundation of an, 733
  Election of Dr. Eugen Sanger as president, 733
Astronomical Union, International : Appointment of Prof. P. Th. Oosterhoff as assistant general secretary, 683
Astrup, Dr. Tage, and Alkjaersig, Norma : Quaternary Detergents and the Activity of Trypsin and Plasmin, 565
Atkinson, H. F. (Armstrong, W. G., and) : Transamination in the Human Tooth, 695
Atomic Scientists Association : Annual General Meeting, 1027
Attlee, C. R. : Honorary degree of LL.D. of the University of Glasgow conferred on, 155
Attwood, E. A. : Awarded a Postgraduate Agricultural Scholarship by the Ministry of Agriculture and Fisheries, 683
Attwood, P. R. : Awarded a Postgraduate Agricultural Scholarship by the Ministry of Agriculture and Fisheries, 683
Atwood, K. C. : Genes and Mutations, 733
Auber, L., and Appleyard, H. M. : Surface Cells of Feather Barbs, 736
Audrieth, Ludwig F. (edited by) : Inorganic Syntheses, Vol. 3, *review* by A. J. E. W., 399
Audubon Water Bird Guide (Richard H. Pough), *review* by Frances Pitt, 355
Auerbach, C. : Genes and Mutations, 732
Aughtie, Dr. F. : Recent Developments and Techniques in the Maintenance of Standards, 594
Austin, C. R. : Activation and the Correlation between Male and Female Elements in Fertilization, 558
Australian Chemical Institute, Royal : First issue of *Reviews of Pure and Applied Chemistry*, 188
Australian National University, Canberra : Election of Lord Bruce of Melbourne as first chancellor, 276
  Appointment of E. K. Inall as a Research Fellow in the Department of Nuclear Physics, 276
  Appointment of Dr. P. A. P. Moran to the first chair of statistics in the Research School of Social Sciences, 320
  Appointment of Dr. P. B. Treacy as a Research Fellow in the Department of Nuclear Physics, 899
Avery, J. H., and Ingram, A. W. K. : Laboratory Physics, *review* by S. Weintroub, 355
Aylett, P. D. : Awarded a Student's Premium of the Institution of Electrical Engineers, 103
Aylward, Dr. Francis : Chemicals in Food, 778
  A Philosophy of Nutrition, 1100

RP R296

BABISTER, A. W. : Appointed lecturer in aeronautical engineering at the University of Glasgow, 1068
Bacharach, A. L. : The Application of Statistical Methods to Chemistry, 1073, 1074
Bacq, Prof. Z. M., and Herve, A. : Protective Action of Methylamine against X-Irradiation, 1126
Bacteriology (Applied), Society for : Annual General Meeting and Conference, 730
  Symposium on the Chemistry and Bacteriology of Silage, 730
  Symposium on the Effect of Cold on Micro-organisms, 990
Badcock, Ruth M. : Appointed assistant lecturer in biology at the University College of North Staffordshire, 19
Baddeley, Dr. G., and others : A Novel Connexion between Electrostatic Interaction and Intramolecular Configuration, 386
Baddiley, James : *Obituary*, 767
Baden-Powell, D. F. W. : The Interglacial Beds at Hoxne, Suffolk, 701
Badger, Dr. G. M., and Beecham, A. F. : Isolation of Tetrahydroharman from *Petalostylis labicheoides*, 517
Badrick, F. E., and others : Inactivation of Adrenotropic Hormone (ACTH) by Plasma, 206
Baertschi, Dr. P. : Relative Abundances of Oxygen and Carbon Isotopes in Carbonate Rocks, 288
Bagenal, T. B. (Gauld, D. T., and) : A High-speed Tow-net, 523
Bailey, A. E. : Automatic Control, 405
Bailey, Dr. G. L. J. : Technique of Electron Microscopy, 819
Bailey, Dr. K. C. : *Death of*, 543 ; *obituary* by Dr. J. H. J. Poole, 679
Bailey, Prof. V. A. : Awarded the T. K. Sidey Medal and Prize for 1951 of the Royal Society of New Zealand, 726
Baillie, Rev. John : Natural Science and the Spiritual Life, *review* by the Very Rev. Dr. W. R. Matthews, 968
Bain, W. C. : Degree of Ph.D. of the University of Aberdeen conferred on, 103
Bainbridge, R. (Hardy, Prof. A. C., and) : Vertical Migration of Plankton Animals, 327
Baird, Kathleen J. : Multiple Infection of Clover Plants by Strains of the Nodule Organism in the Field, 116
Baird, R. H., and others : *Mytilicola intestinalis*, Steuer, in the
Flat Oyster (*Ostrea edulis*), 560
Baker, Dr. H. G., and Jackson, W. : Cytology of the Ecotypes o
Melandrium dioicum (L. emend.) Coss. & Germ., 747
Baker, Prof. J. F. : The Education and Training of the Engineer
Baker, Dr. John R. : The 'Golgi Substance', 1089
Baker, Dr. J. W. : Electronic Theories of Organic Chemistry,
Baker, P. B., and others : Isolation of 17-Hydroxycortico
17-Hydroxy-11-dehydrocorticosterone from Hog Adren
Balaban, Dr. I. E. : *Obituary*, 16
Balankura, N. K. : Development of the Mammalian Lymphatic Sy
Baldi, Prof. E. : *Obituary* by Prof. H. Munro Fox, 496
Baldwin, R. W. : Awarded a Dorothy Temple Cross Research
Fellowship in Tuberculosis by the Medical Research Counc
Baldwin, T. H., and others : Effects of Ionizing Radiations upon
Deoxyribosenucleoprotein Fibres, 694
Balfour, F. M. (1851–82), 812
Ball, Dr. J., and others : Biophysical Studies of Rheumatoid Co
Tissue, 493
Ball, R. H. : Appointed an agricultural officer, Nigeria, 641
Balmain, Judith H., and others : Stimulation by Insulin of *in vitro*
thesis by Mammary Tissue studied with Carbon-14 and
1083
Bamford, Dr. C. H., and Hanby, W. E. : Structure of Synthetic Poly
and Proteins, 340
  The Lotmar–Picken X-Ray Diagram of Dried Muscle, 1085
Bamford, Dr. C. H., and others : Resistant Peripheral Membran
Keratin Fibres, 824
Banda, Dr. Garcia de la : Awarded a Ramsay Memorial Fellow
chemical research, 983
Banerjee, Basudev (Moewus, Prof. Franz, and) : Effect of *cis*-Cinna
and some Isomeric Compounds on the Germination of Zy
Chlamydomonas, 561
Banerjee, Dr. B. K. : Awarded an Imperial Chemical Industrie
Research Fellowship by the National Institute of Sciences
498
Banerjee, Prof. B. N. (Ramakrishnan, Dr. C. V., and) : Mould Lipas
of Addition of Vitamins and Sterol to the Cake Medium
Growth and Activity of the Lipolytic Mould, 917
Bannister, Dr. F. K. : Title of reader in thermodynamics at the U
of Birmingham conferred on, 940
Baradi, A. F., and Bourne, Dr. G. H. : Localization of Gustatory a-
tory Enzymes in the Rabbit, and the Problems of Taste a
977
Baranyovits, Dr. F. : Fly Reactions to Insecticidal Deposits—a N
Technique, 960
Barber, C. R. : Recent Developments and Techniques in the Ma
of Standards, 596
Barbosa, Prof. O. : Elected president of the Brazilian Geological
for 1951–52, 899
Barcia-Goyanes, Carlos (Govaerts, Dr. J., and) : Radiochemical D
tion of Chromium, Vanadium and Molybdenum by means
active Silver, 198
Barker, Dr. C. C. : Racemization of N-Acylaspartic Acids, 908
Barker, P. N. : Awarded a Postgraduate Agricultural Scholarsh
Ministry of Agriculture and Fisheries, 683
Barker, S. A., and others : Carbohydrate Primers for *Q*-Enzyme,
Barkworth, H. : Methylene Blue Test, 731
Barlow, F. O. : *Obituary* by W. N. Edwards, 1103
Barnard, Dr. Chester I. : Elected chairman of the National Scie
of the National Science Foundation, 1066
Barnard, Dr. G. : Ethical Problems of the Scientific Worker, 111
Barnes, Dr. J. : Chemotheraphy of Tuberculosis, 540, 541
Barnett, Dr. A. J. G. : Chemistry and Bacteriology of Silage, 730
Barrass, R. : Appointed an assistant lecturer in geology at the
College of North Staffordshire, 19
Barrell, H. : Recent Developments and Techniques in the Ma
Standards, 595
Barrett, A. S. D. (Beckett, L. G., and) : Freezing and Drying, 8
Barrett, P. A., and others : Geometrical Isomers in a Serie
tamines, 204
Barrett, S. A. : Appointed lecturer in zoology at the University
1068
Barrow, R. F. (Welti, D., and) : Ultra-Violet Absorption Spect
and Indium Monofluorides, 161
Barry, Dr. V. C. : Chemotherapy of Tuberculosis, 540
Barth, Alan : The Loyalty of Free Men, 1051
Bartlett, G. D. N. : Appointed principal agricultural assista
147
Bartlett, H. H. : Radio-carbon Datability of Peat Marl, Caliche
logical Materials, 725
Barton, R. A. : Is Age of Parents Important in Sheep?, 37
Barton, Dr. T. H. : Appointed lecturer in electrical engin
University of Sheffield, 726
Bask, —. : Mechanical Plant for Electricity Power Stations,
Bassett, G. A. : Technique of Electron Microscopy, 820
Basu, D. : Awarded a National Institute of Sciences of India
Fellowship, 498
Basu, Dr. Sadhan : Viscosity of Sodium Thymonucleate, 34
Batchelder, Charles Foster : Published Writings of C. J.
1929), 368
Batchelor, Dr. G. K., and others : Adams Prize for 1949–50
sity of Cambridge awarded jointly to, 19
Bates, C. R. : Awarded a Student's Premium of the Institut
Engineers, 103
Bates, D. R. : Degree of D.Sc. of the University of London c
940
Bates, Prof. L. F. : Some Aspects of Discharge Physics, 140
  Appointed senior scientific adviser on civil defence, No
  Region, 984
  Applications of Physics in the Diagnosis and Treatment of
Bates, L. M., and others : 1,000-Curie Cobalt-60 Units for Radiatio

NAME INDEX

Fulton, Dr. J. D. : The Evaluation of Chemotherapeutic Substances, 865
Furberg, S. E. : The Decay Scheme of Zinc-65, 1005
Fürth, Dr. R. : Physics of Social Equilibrium, 546, 1048
Fuson, Prof. Reynold C. : Advanced Organic Chemistry, *review* by Dr. R. A. Raphael, 262

GABRIELI, Dr. Elemér R. : Effect of Antihistamine on the Reticulo-endothelial System—Investigation of Reticulo-endothelial Function with the aid of Radioactive Chromium Phosphate, 467
Gage, J. C. (Diggle, W. M., and) : Cholinesterase Inhibition by Parathion in vivo, 998
Galloway, I. A. : Freezing and Drying, 852
Galloway, L. D., and Burgess, Dr. R. : Applied Mycology and Bacteriology, third edition, revised by L. D. Galloway, *review* by Dr. John Grainger, 7
Galston, Dr. A. W. (Davies, Dr. R. E., and) : Rapid Rate of Turnover of Potassium Ions in Kidney Slices, 700
Gamow, Dr. G. : Hydrogen Exhaustion and Explosions of Stars, 72
Gane, R. : Freezing and Drying, 852
Ganguli, Dr. A. : Awarded an Imperial Chemical Industries (India) Research Fellowship by the National Institute of Sciences of India, 498
Ganguly, B. K., and Mukherji, Dr. S. M. : A New Synthesis of *p*-Terphenyl and its Derivatives, 1003
Garde, A. : Automatic Control, 405
Garden, J. F. : Appointed veterinary officer, Tanganyika, 368
Garner, Prof. F. H. : Mixing and Agitating in Liquid Media, 376
  The Training of a Technologist, 724
  Appointed a member of the Gas Council Research Committee, 858
  Rheology of Films and Surfaces, 945
Garner, P. G. : Awarded an *Endeavour* Third Prize, 274
Garner, Prof. W. E. : Appointed senior scientific adviser on civil defence, South Western Region, 984
Garrett, C., and others : 1,000-Curie Cobalt-60 Units for Radiation Therapy, 1035
Garrett, Sir Wilfrid : People at Work, 987
Garrod, Dr. O. : Awarded a Rockefeller Travelling Fellowship in Medicine by the Medical Research Council, 189
Garside, Dr. J. E., and Jackson, B. : Polyhedral Diffusion Flames, 1085
Garven, A. B. : Appointed a lecturer in civil engineering at the University of Glasgow, 1068
Gas Council : Research Centre at Birmingham, 145
Gas Council Research Committee : Appointment of additional members, 858
Gas Turbine Technology, School of : Appointment by Power Jets (Research and Development), Ltd., of G. C. R. Mathieson as senior lecturer, 147
Gáspár, R. (Gombás, Prof. P., and): Solution of the Thomas–Fermi–Dirac Equation, 122
Gatenby, Prof. J. Bronte : Appointed visiting professor of zoology in the Faculty of Science, King Farouk University, Alexandria, 500
Gates, S. B. : Awarded the Silver Medal of the Royal Aeronautical Society, 498
Gauld, D. T., and Bagenal, T. B. : A High-speed Tow-net, 523
Gaunt, H. M., and Craggs, Dr. J. D. : Pre-Breakdown Discharges in D.C. Positive Point-to-Plane Corona, 859
Gaydon, Dr. A. G. : Spectrochemical Analysis, *review*, 5
Gee, R. W. : Awarded a Student's Premium of the Institution of Electrical Engineers, 103
Gellhorn, Prof. Walter : Security, Loyalty and Science, 305
Gellner, O. H., and Richardson, Dr. F. D. : Reduction of Ferrous Oxide, 23
Gelotte, Dr. Bertil : Paper Chromatography of Muscle Tissue Constituents—A Phosphate-absorbing Protein from Muscular Tissue, 461
Gelotte, Dr. Bertil (Snellman, Dr. Olle, and) : Paper Chromatography of Muscle Tissue Constituents—Paper Chromatography of Adenosine Phosphates, 461 ; The Prosthetic Group of Actin, 462
General Register Office : Census 1951, England and Wales, Preliminary Report, 580
Geodesy, Photogrammetry and Cartography, Institute of : Established in the Ohio State University, Columbus, 588
Geoghegan, Dr. M. J. : Unicellular Algae as a Source of Food, 426
Geographic Society, National, and the Royal Ontario Museum, Toronto : Joint Expedition to Chubb Crater in Northern Canada, 145
Geographical Association : Annual Conference, 1027
Geographical Society, Royal : Christmas Lectures, 984
Geological Survey Department, Tanganyika : Appointment of R. A. Sutton as geo-chemist, 276
George, Dr. P. H. : Senses and Behaviour of Animals, 644
George, Dr. P., and Irvine, D. H. : Reaction of Metmyoglobin with Hydrogen Peroxide, 164
George, Prof. T. N. : Surveys of Under-Developed Areas, 586
George, Wilma : Elementary Genetics, *review* by Dr. G. Pontecorvo, 887
Georgi, Dr. J. : Zur Frage der Namengebung in der Antarktis, 275
Gerber, Dr. J. H. : Awarded the Langley Memorial Prize of the London School of Hygiene and Tropical Medicine, 899
German Hydrographic Institute, Hamburg : Annual Report for 1950, 1027
German Society for Electron Microscopy : Third Annual Conference (Dr. G. Liebmann), 70
Gerretsen, Dr. F. C., and Haagsma, Netty : Occurrence of Antifungal Substances in *Brassica rapa*, *Brassica oleracea* and *Beta vulgaris*, 659
Gersh, I. : Freezing and Drying, 853
Gibb, Sir Claude : 2,000 Years of Engineering, 229
Gibson, J. E. : Appointed a lecturer in civil engineering at the University of Glasgow, 1068
Gibson, N. A. (Dwyer, Dr. F. P., and) : Dissociation of Complex Ions in Non-Aqueous Solvents, 787
Giffard, E. O. : Geography in the Service of Mankind, 314
Gilbert, L., and others : Degradation of Deoxyribonucleic Acid by a 'Nitrogen Mustard', 985
Gilbert, L. F. : Glasgow Chemists, *review*, 969
Gilbreth, Dr. Lillian M. : Elected an honorary fellow of the British Institute of Management, 63
Gilding, Prof. H. P. : Physiology of the Capillaries, 230
Giles, N. H. : Genes and Mutations, 732
Gill, Sir Archibald : Electrical Devices on Board Ship, 238
  Retirement as engineer-in-chief of the Post Office, 276
Gill, Edmund D. : Antiquity of the Australian Aborigines, 982
Gilles, K., and others : A Colorimetric Method for the Determination of Sugars, 167
Gillman, H. : Appointed deputy director of agriculture, Nyasaland, 641
Gilmour, J. S. L. : The Complete Garden Handbook, *review*, 52
  The Development of Taxonomic Theory since 1851, 400 ; *erratum*, 500
Gilson, H. C. : Zoology at the Marine, Freshwater and Field Stations, 548
Ginsberg, Dr. Hans (Fulda, Dr. Wilhelm, und) : Tonerde und Aluminium, Ergebnisse und Erfahrungen aus der Betriebspraxis 1920–1950, Teil I, *review*, 397
Giri, Prof. K. V., and Prasad, A. L. N. : Separation of Enzymes by Paper Chromatography, 786
Glaciological Society, British : Election of Officers for 1952, 1027
Glaeser, Mlle. : Cation Exchange and Clay Mineral Structure, 107
Glaister, Dr. E. : Appointed to the University of London readership in mechanical engineering at the Imperial College of Science and Technology, 368
Glascock, Dr. R. F. : Estimation of Radioactive Hydrogen as Tritiobutane in the Geiger Counter, 121
Glascock, Dr. R. F., and others : Stimulation by Insulin of *in vitro* Fat Synthesis by Mammary Tissue studied with Carbon-14 and Tritium, 1083
Glaser, Prof. E. M., and McCance, Prof. R. A. : Life and Work in Extreme Environmental Conditions, 363
Glasgow Art Gallery and Museum : Booklet on Animals of Scotland in the 'Habitat Court', 413
Glauert, Audrey M. : Superposition Effects in Multiple-Beam Interference Fringes, 861
Glazko, Dr. A. J., and Dill, W. A. : A Colour Reaction distinguishing between Adrenaline and *nor*-Adrenaline on Paper Chromatograms, 32
Gleen, Dr. H. : Microbiological Oxidation of Ammonium and Thiocyanate Ions in Soil, 117
Glegg, D. B. : Awarded a Swan Premium of the Institution of Electrical Engineers, 103
Gleming, G. A., and others : Selenium Toxicity associated with an Irish Soil Series, 881
Gluckauf, Dr. E. : Appointed a Deputy Chief Scientific Officer in the Scientific Civil Service, 497
Goetzel, Dr. Claus G. : Treatise on Powder Metallurgy, *review* by H. W. Greenwood, 133
Gold Coast College of Arts, Science and Technology : Appointment of Prof. J. P. Andrews as vice-president and professor of physics at University College, Ibadan, 17
  Appointment of R. Pattison as head of the Engineering Department in University College, Ibadan, 17
Goldfinger, Prof. P., and others : Induction Periods in Reactions of N-Halogenimides, 30
Goldman, Prof. Stanford : Transformation Calculus and Electrical Transients, *review*, 577
Goldschmidt, R. : Genes and Mutations, 732
Gombás, Prof. P., and Gáspár, R. : Solution of the Thomas–Fermi–Dirac Equation, 122
Goodall, J. E., and Irving, D. B.: Gas-Pressure Cables for High-Voltage Systems, 238
Goodban, J. W. D. : Appointed director of agriculture, British Honduras, 276
Goodey, Dr. T. : Soil and Freshwater Nematodes, *review* by Prof. C. H. O'Donoghue, 801
Gooding, Dr. G. C. : Physiological Problems of Mining, 642
Goodson, F. J. : Mixing and Agitating in Liquid Media, 376
Goodwin, Dr. L. G. : The Evaluation of Chemotherapeutic Substances, 865
Gordon, J. E. : Appointed a Senior Principal Scientific Officer in the Scientific Civil Service, 497
Gordon, Dr. J. J., and Pelly, Janet E. : Estimation of Deoxycorticosterone by a Modified Hagedorn–Jensen Procedure, 603
Gordon, Seton : A Camera in Antarctica, *review*, 52
  Flamingo City, *review*, 621
Gordon Memorial College, Khartoum : Appointment of Prof. N. F. Astbury to the chair of physics, 456
Gorini (Costantino) Foundation for Dairying, Milan, 939
Gorrie, —. : Problems of Marginal Land Farming, 458
Gosselain, P. A., and others : Induction Periods in Reactions of N-Halogenimides, 30
Gotfredsen, Prof. Edvard : British and Danish Medicine in the Seventeenth and Eighteenth Centuries, 867
Goudge, Prof. Thomas A. : The Thought of C. S. Peirce, *review* by F. I. G. Rawlins, 311
Gough, Miss Kathleen : The Ancient Khmer Empire, 777
Gould, F. A. : Report of the Committee on Weights and Measures Legislation, 142
Govaerts, Dr. J., and Barcia-Goyanes, Carlos : Radiochemical Determination of Chromium, Vanadium and Molybdenum by means of Radioactive Silver, 198
Gowan, J. E. (Wheeler, Prof. T. S., and): Name Index of Organic Reactions, 63
Gowans, Dr. J. L. : Awarded a Travelling Scholarship in Medical Science by the Medical Research Council, 189
Grace, Joyce B. : Myxobacteria Mistaken for Nitrifying Bacteria, 117
Grace, Dr. M. A., and others : An Experiment on Nuclear Alignment—the Anisotropy of γ-Radiation from Oriented Cobalt-60 Nuclei, 780
Grafton, Raymond : Awarded a Salter's Fellowship for 1951–52 by the Salter's Institute for Industrial Chemistry, 641
Graham, G. W. : Reduction of Static Electrification by means of Inhibiting Compounds, 871
Grainger, Dr. John : Applied Mycology and Bacteriology, *review*, 7
Grant, A. B. : Antivitamin D Factor, 789
Granville, S. A. : Appointed statistician, Statistics Department, East Africa High Commission, 189
Gray, Prof. C. H. : Degree of D.Sc. of the University of London conferred on, 940
Gray, Prof. J. : Undulatory Propulsion in Small Organisms, 929
Gray, Wm. Hamilton : Honorary fellowship of Heriot-Watt College, Edinburgh, conferred on, 146

Grayson, Dr. L. (Chester, Dr. W., and) : Physical Basis of Internal Calorimetry, 521
Greaves, Dr. R. I. N. Freezing and Drying, 851
Grebenik, E. . 1951 Population Census of England and Wales, 580
Green, A. F., and others : Geometrical Isomers in a Series of Antihistamines, 204
Green, Dr. A. L. : *Obituary* by Dr. R. v. d. R. Woolley, 768
Green, Prof. H. N., and others : Kidney Citrate Levels in Nucleotide Shock, 297
Green, J. O. : American Forage and Pasture Crops, *review*, 575
Green, R. N. : Appointed agricultural officer, Somaliland Protectorate, 641
Greenberg, Sidney : The Infinite in Giordano Bruno, *review* by F. I. G. Rawlins, 848
Greene, Dr. Herbert . Surveys of Under-Developed Areas, 586
Greene-Kelly, R. : Cation Exchange and Clay Mineral Structure, 107
Greenkeeping Research, Board of . To be known in future as the Sports Turf Research Institute, 456
Greensmith, H. W., and Rivlin, R. S. : Measurements of the Normal Stress Effect in Solutions of Polyisobutylene, 664
Greenwald, Miss Selma : Changes in Lattice Constants of Cr_2O_3 near the Curie Temperature, 379
Greenwich Observatory, Royal . Annual Report for 1950–51, 418
Greenwood, Allan Negative Point-to-Plane Corona—a New Mode of the Discharge, 41
Greenwood, H. W. Science and Technology of Powder Metallurgy, *review*, 133
Greenwood, Dr. N. N., and Martin, R. L. : Discontinuities in Supercooled Ionic Melts, 344
Gregg, Dr. Mary : Resignation as lecturer in botany at the University of Birmingham, 682
Gregg, Dr. S. J. : Cation Exchange and Clay Mineral Structure, 107, 108
Gregory, Prof. H. S., and Sherif, I. I. : A New Method for Measuring the Atomic Heats of Gases, 1123
Gregory, William King (arranged and edited by) . The Anatomy of the Gorilla, the Studies of Henry Cushier Raven, *review*, 926
Greig, Prof. James : Electromagnetism for Engineers, *review*, 4
    Honorary fellowship of Heriot-Watt College, Edinburgh, conferred on, 146
Grenville-Wells, H. J. : A New Method of Observing Compton and other Incoherent X-Ray Scattering in Crystals, 291
Gridgeman, N. T., and others : Pure *All-trans* Vitamin A Acetate and the Assessment of Vitamin A Potency by Spectrophotometry, 598
Griffith, G. W. S. : Awarded a John Hopkinson Premium of the Institution of Electrical Engineers, 103
Griffiths, Dr. Ezer : Life and Work in Extreme Environmental Conditions, 363
Griffiths, Dr. J. H. E. Awarded the Charles Vernon Boys Prize for 1951 by the Physical Society, 588 ; work of, 588
Griffiths, Miss M. V. : Life and Work in Extreme Environmental Conditions, 364
Grimshaw, Dr. H. C. : Appointed an honorary lecturer in mining at the University of Sheffield, 726
Grinsted, W. A. : Appointed director of the British Caribbean Meteorological Service, 769 ; work of, 769
Gristwood, A. F. : Awarded a Postgraduate Agricultural Scholarship by the Department of Agriculture for Scotland, 589
Gross, Dr. Nicol : Appointed assistant director of research of the British Welding Research Association, 19
Gruse, Dr. W. A. : Pittsburgh Award of the Pittsburgh Section of the American Chemical Society made to, 1104 ; work of, 1104
Guenault, Dr. E. M. : Appointed an honorary lecturer in mining at the University of Sheffield, 726
Guenther, Dr. Ernest : The Essential Oils, Vol. 4, *review* by Dr. E. G. Kellett, 395
Guild, J. : Colours and How to See Them, *review*, 51
    Diffraction Gratings, 68, 69
Guillan, Lieut.-Colonel S. C., and Askew, Major W. G. (edited by) Metallurgical Abstracts (General and Non-Ferrous), Vol 16, 1948–49, *review* by Dr. W. Hume-Rothery, 1016
Gunn-Russell, C. . Awarded an extra Ambrose Fleming Premium of the Institution of Electrical Engineers, 103
Gunter, R., and others Spectral Reflexion Factor of the Cat's Tapetum, 293
Gustafson, Torsten : Density of Tracks of Protons and Mesons in Photographic Emulsions, 377
Gustafsson A. Genes and Mutations, 733
Guyénot, Prof. Emile : Elected a non-resident member of the Paris Academy of Sciences, 63, 413, 940
Gyarfas, Miss E. C. (Dwyer, Dr. F. P., and) : Preparation of the Optical Forms of Tris-Acetylacetone Cobalt III, 29

HAAGSMA, Netty (Gerretsen, Dr. F. C., and) : Occurrence of Antifungal Substances in *Brassica rapa*, *Brassica oleracea* and *Beta vulgaris*, 659
Hacking, Sir John : Generation, Transmission and Distribution of Electricity, 238
Haddow, Prof. A. : The Chemistry of Cell Division, 462
Haden-Guest, Lord : Ethical Problems of the Scientific Worker, 1112, 1113
Hafez, Dr. E. S. E. : Inhibitory Action of Artificial Light on the Sexual Season of the Ewe, 336
    Sexual Season in Ewe Lambs, 1046
Hagihara, Prof. Y. : *Obituary* of Prof. Rikitu Sekiguti, 1065
Hahn, Otto : New Atoms, *review* by Prof. O. R. Frisch, 6
Haigh, C. P. : A Toroidal Geiger Counter, 246
Haine, K. E. : Vegetative Propagation from the Broccoli Curd after Suppression of Flowering, 919
Haine, M. E. : Technique of Electron Microscopy, 820
Haines, Dr. R. Wheeler : Appointed senior lecturer in anatomy at the University of Sheffield, 103
Hales, Prof. A. L. : Crustal Layers of the Earth, 163
Halkerston, I. D. K., and others : Inactivation of Adrenotropic Hormone (ACTH) by Plasma, 206
Hall, Prof. A. A. Appointed director of the Royal Aircraft Establishment, Farnborough, 19
Hall, A. N., and others . Chromatographic Detection of Pyruvic, Dimethylpyruvic and α-Ketoglutaric Acids in Cultures of *Aspergillus niger* on various Substrates, 1042
Hall, Dr. C. C. : Appointed a Senior Principal Scientific Officer in the Scientific Civil Service, 498
Hall, Dr. D. A. : A Simplified Coupled Filter System for Adsorption Chromatography, 124
    Elastin from Human Tissue and from Ox Ligament, 513
Hall, Dr. D. A., and Wewalka, Dr. F. : Movement of Proteins on Filter Paper, 685
Hall, Dr. D. A. (Fewster, Mona E., and) : Application of Buffered Solvent Systems to the Detection of Aromatic Acids by Paper Partition Chromatography, 78
Hall, Dr. R. T. W. : Resignation as lecturer in chemical engineering at the University of Birmingham, 940
Hall, W. Keith, and others . Adsorption of Water and Methanol on Coal, 124
Halle, Prof. T. G. : Honorary degree of LL.D. of the University of Glasgow conferred on, 155
Hallett, Prof. H. F. : Title of professor emeritus of philosophy in the University of London conferred on, 147
Halling, F. : Awarded a Clayton Fellowship of the Institution of Mechanical Engineers, 236
Halmos, Prof. Paul R. : Measure Theory, *review* by Prof. H. T. H. Piaggio, 260
Halpern, Prof. Otto : Detection of Circularly Polarized γ-Rays and the Production of Polarized Electrons, 782
Halsbury, Lord : Re-appointed a member of the National Research Development Corporation, 545
Ham, Prof. A. W. (Mosbaugh, M. M., and) . Stimulation of Bile Secretion in Chick Embryos by Cortisone, 789
Hamaguchi, Kozo, and others : Monolayers of Synthetic Protein Analogues, 165
Hamer, D. : Twelfth International Congress of Pure and Applied Chemistry, 766
Hamerslag, Frank E. The Technology and Chemistry of Alkaloids, *review*, 311
Hamilton, J. K., and others : A Colorimetric Method for the Determination of Sugars, 167
Hammond, Dr. John : Tropical Animal Nutrition, *review*, 440
    Limits to Intensive Production in Animals, 490
    Ethical Problems of the Scientific Worker, 1113
Hamner, Dr. C. L., and others : Chlorophyll Inhibition and Growth Regulation by several Tetronic Acid Derivatives, 85
Hanby, W. E. (Bamford, Dr. C. H., and) : Structure of Synthetic Polypeptides and Proteins, 340
    The Lotmar–Picken X-Ray Diagram of Dried Muscle, 1085
Hanby, W. E., and others : Resistant Peripheral Membranes of the Keratin Fibres, 824
Handa, Takashi, and others : Electrical Conductivity and Magnetic Susceptibility of Ovalene, 520
Hanes, Dr. Charles S. : A Convenient 'Hanging-drop' Glass Electrode Unit, 566
Hankey, Lord : The Science and Art of Government, 571
Hanna, Prof. S. S. (Class, C. M., and) : The Lithium-7 Nucleus, 429
Hannan, R. S., and Lea, C. H. : Reaction between Glucose and the Terminal Amino Group of Lysine, 744
Hansford, R. F. : Awarded a Bronze Medal of the Institute of Navigation, 813
Hanson, A. W., and others : Fourier Synthesis by Optical Interference, 160
Harbord, Vernon : Elected president for 1952–53 of the Institution of Mining and Metallurgy, 369
Harding, Dr. A. R. : Appointed a research fellow in metallurgy at the University of Birmingham, 940
Harding, H. G. W., and others : Spectral Reflexion Factor of the Cat's Tapetum, 293
Harding, H. J. B. : The Education and Training of the Engineer, 15
Harding, Dr. J. P. : Zoology at the Marine, Freshwater and Field Stations, 547
Harding, Joan R. : Prehistoric Sites on the North Cornish Coast, 589
Hardwick, J. (Franklin, E., and) : Electronics in Nuclear Science and Engineering, 949
Hardy, Prof. A. C., and Bainbridge, R. : Vertical Migration of Plankton Animals, 327
Hardy, E. J. R. : Awarded a Student's Premium of the Institution of Electrical Engineers, 103
Hargreaves, —. : Library Service, 330
Harington, Sir Charles : Elected an honorary fellow of the Royal Society of Edinburgh, 61
Harnik, E., and others : X-Ray Crystallographic Measurements on some Compounds showing Intramolecular Overcrowding, 158
Harper, P. C. : Awarded a Postgraduate Agricultural Scholarship by the Department of Agriculture for Scotland, 589
Harrap, B. S., and others : Influence of Salt on the Size and Shape of a Protein–Detergent Complex, 910
Harries, W. L. Some Aspects of Discharge Physics, 141
Harris, Dr. G. W., and others : Terminology for Use in Lactational Physiology, 421
Harris, Dr. H., and others : Glucose, Glutamate and Succinate Oxidation in Brain, 914
Harris, H. (Datta, S. P., and) : Dietary Origin of Urinary Methyl-Histidine, 296
Harris, Prof. J. E. : Senses and Behaviour of Animals, 643
Harris, J. G. : Appointed assistant conservator of forests, Nigeria, 641
Harris, Dr. R. J. C. : Preservation of Biological Materials by Freeze-Drying, 851
Harris, T. A. B. : The Mode of Action of Anaesthetics, *review* by Dr. H. Roy Blades, 1098
Harrison, A., and others . Radiochemical Techniques in Analysis, 154
Harrison, G. P., and others : Mode of Action of Antibiotics in Stimulating Growth of Chicks, 332
Harrison, Prof. J. W. Heslop : British Orchids, *review*, 353
Harrison, Marion F. . Relation between Polyploidy and the Amounts of Deoxynucleic Acid per Nucleus in the Liver and Kidney of Adult Rats, 248

NAME INDEX

Harrison, Marion F. (Brown, Lucy M., and) : Effect of a Single Injection of Carbon Tetrachloride upon the Activity of the Pseudo-cholinesterase in the Liver and Serum of Male and Female Rats, 83
Harrison, Dr. R. J.: Appointed head of the Department of Anatomy at the London Hospital Medical College, with the title of University of London reader in anatomy, 683

Humphrey, Dr. J. : The Evaluation of Chemotherapeutic Substances, 865
Humphries, Lieut.-Colonel G. J : Surveys of Under-Developed Areas, 585
Humphries, J. : Second International Congress on Astronautics, 733
Hunt, Dr. J. N. : Awarded a Rockefeller Travelling Fellowship in Medicine by the Medical Research Council, 189
Hunter, —. : Scientific Management, 506
Hunter, J.: Appointed a lecturer in mathematics at the University of Glasgow, 1068
Hunter, Prof. L. : Appointed a scientific adviser on civil defence, North Midland Region, 984
Hunter, Lois, and others: A Further Example of *Kidd* (Jk^b) Hæmagglutinin, 790
Hurrell, H. G. : Movement of Swifts, 157
Hurst, Dr. H. E. : *Obituary* of P. A. Curry, 981
Hutchings, C. D. : Appointed deputy director of agriculture (Extension Services), Jamaica, 147
Hutchinson, George Evelyn : Survey of Existing Knowledge of Biogeochemistry, 3, The Biogeochemistry of Vertebrate Excretion, *review* by Sir James Scott Watson, 925
Hutchison, T. W. : Appointed to a University of London readership in economics at the London School of Economics and Political Science, 368

IKIN, Elizabeth W., and others: Discovery of the Expected Hæmagglutinin, Anti-Fy^b, 1077
Iland, Dr. C. : Chemotherapy of Tuberculosis, 540
Illuminating Engineering Society : Leon Gaster Memorial Premium for 1951 awarded to H. W. Cumming, 641
Imperial Cancer Research Fund : Forty-eighth Annual Report, 417
Imperial College of Science and Technology, London : Title of professor of applied mechanics in the University of London conferred on Dr Hugh Ford, 18
    Title of professor of technical optics in the University of London conferred on Dr. W. D. Wright, 18
    Title of reader in inorganic chemistry in the University of London conferred on Dr. A. J. E. Welch, 236
    Summer School on Relaxation Methods, 236
    Appointment of Dr. E. Giaister to the University of London readership in mechanical engineering, 368
    Appointment of A. G. Smith to the University of London readership in applied thermodynamics, 770
Imperial College of Tropical Agriculture : Appointment of A. B Killick as professor of agriculture and director of studies, 234, 638, 641
Imperial Forestry Institute, Oxford : Annual Report for 1949–50, 983
Imperial Smelting Corporation, Ltd. : Production of Fluorine Gas compressed into steel cylinders, 236
Inall, E. K. : Appointed a Research Fellow in the Department of Nuclear Physics of the Australian National University, Canberra, 276
Inches, J. Morison : Honorary fellowship of Heriot-Watt College, Edinburgh, conferred on, 146
Indian Institute of Technology, 411
Indian Science Congress Association : 'Scicong' Memoranda for Unesco, 589
Indian Veterinary Research Institute : Diamond Jubilee Celebrations (Dr. G Lapage), 287
Industrial Psychology, National Institute of : The Foreman, a Study of Supervision in British Industry, *review* by T. H. Hawkins, 671
Industrias Quimicas, Sindicato Vertical de : Conference on Safety and Hygiene in Chemical Industry from the Point of View of the Manager, Technician and Operative, 641
Ingelstam, Erik : A Highly Sensitive Phase-Contrast Refractometer for Liquids and Gases, 960
Inghram, Mark G., and others : Age of Tektites, 432
Inglis, J. S. S. : Appointed lecturer in animal husbandry at the University of Glasgow, 1068
Ingold, Prof. C. K., and others : Wagner Changes, Synartetic Acceleration and Synartetic Ions, 65
    A New View of the Arylhydroxylamine Rearrangement, 909
Ingram, A. W. K. (Avery, J. H., and) : Laboratory Physics, *review* by S. Weintroub, 355
Ingram, Dr. D J. E. : Appointed research fellow in the Department of Electronics, University College, Southampton, 984
Ingram, Dr. M. : Anaerobic Bacteria in Whale Flesh, 731
    Effect of Cold on Micro-organisms, 990, 991
Inkley, G. W. (Dickinson, Dr. Lois, and) : Use of a Sheep Abortion Virus as a Test Virus for Chemotherapy Work, 37
Inokuchi, Hiroo, and others : Electrical Conductivity and Magnetic Susceptibility of Ovalene, 520
Insects (Social), International Union for the Study of the Behaviour of, 898
Institut pour l'Encouragement de la Recherche scientifique dans l'Industrie et l'Agriculture : Rapport Annuel 1950, 420
Inter-African Bureau of Epizootic Diseases : To be set up in Kenya by the Commission for Technical Co-operation in Africa south of the Sahara, 1025
    Appointment of W. G. Beaton as director, 1025
Inter-Planetary Society, British : Second International Congress on Astronautics, 369
Inter-University Council for Higher Education in the Colonies : Third Report 1949–50 (Colonial Office), 591
International Association of University Professors and Lecturers : Conference of the, 236
    Report on Recurrent Long Leave, 509
    Report on Student Health Services, 320
International Astronautical Federation : Foundation of an, 733
    Election of Dr. Eugen Sanger as president, 733
International Astronomical Union : Appointment of Prof. P. Th. Oosterhoff as assistant general secretary, 683
International Council of Scientific Unions : Annual Meeting, 938
International Federation for Documentation : Eighteenth Conference, 1071
International Institute of Administrative Sciences and Unesco : National Administration and International Organization, a Comparative Survey of Fourteen Countries, 797
International Scientific Film Association : Fifth Congress, 276
International Society of Plant Morphologists : Publication of *Phytomorphology*, 1067
International Society of Soil Science : Joint meeting of Commissions 2 (Soil Chemistry) and 4 (Soil Fertility and Plant Nutrition), 369
International Union of Crystallography : Congress at Stockholm (Dr. H. Lipson), 501
International Union for the Study of the Behaviour of Social Insects, 898
Iredale, Tom : Birds of Paradise and Bower Birds, *review* by Dr. A. J. Marshall, 135
Iron and Steel Institute, and others : Symposium on Metallurgical Applications of the Electron Microscope, *review* by F. C T., 179
    Symposium on the Corrosion of Buried Metals, 456

Iron and Steel Research Association, British, and others : Symposium on the Corrosion of Buried Metals, 456
Irvine, D. H. (George, Dr. P., and) : Reaction of Metmyoglobin with Hydrogen Peroxide, 164

Katz, Dr. Bernhard : Appointed to the University of London chair of biophysics at University College, 18
Kawerau, Dr. E., and Wieland, Prof. T. . Conservation of Amino-acid Chromatograms, 77
Kaye, Dr. M. A. G. : Appointed lecturer in biochemistry at the University of Sheffield, 19
Kealy, W. A. (Medlock, R. S.) : Electronics in Nuclear Science and Engineering, 949
Kealy, T. J., and Pauson, Dr. P. L. : A New Type of Organo-Iron Compound, 1039
Kearney (M. Theodore) Foundation of Soil Science endowed in the College of Agriculture of the University of California, 938
Keast, J. H. : Appointed assistant director of survey, Nigeria, 189
Keddie, R. M. : Chemistry and Bacteriology of Silage, 731
Keech, M. A. : Awarded a Postgraduate Agricultural Scholarship by the Ministry of Agriculture and Fisheries, 683
Keen, Dr. B. A. : The East African Agriculture and Forestry Research Organization, 674
Keene, Prof. M. F. Lucas : Title of professor emeritus of anatomy in the University of London conferred on, 147
Keilin, Prof. D. : Awarded the Copley Medal for 1951 by the Royal Society, 856, 1017
Keilin, Prof. D., and Hartree, Dr. E. F. : Relationship between Hæmoglobin and Erythrocruorin, 266
Kekwick, L. O. : Elected president of the Oil and Colour Chemists' Association, 235
Kellett, Dr. E. G. : The Essential Oils Industry, *review*, 395
Kellgren, Dr. J. H., and others : Biophysical Studies of Rheumatoid Connective Tissue, 493
Kelly, Dr. Harry C. : Appointed assistant director for the Division of Scientific Personnel and Education of the National Science Foundation, Washington, 367
Kemp, Miss P. M. : Awarded a Leverhulme Research Fellowship, 19
Kendall, David G. : Theory of Probability and Statistics, *review*, 217
Kendall, Prof. James : Elected president of the Royal Society of Edinburgh, 814
Kendall, Prof. M. G. : *Obituary* of G. Udny Yule, 542
Kendrick, D., and others : Catalytic Conversion of a Dione into Deeply Coloured Polyenes, 459

NAME INDEX

Kennedy, Dr. A. J. : Appointed Armourers and Brasiers' Company Research Fellow at the Royal Institution, 189
Kennedy, Dr. G. C. : Awarded a Rockefeller Travelling Fellowship in Medicine by the Medical Research Council, 189
  Fertility, 286
  Chemotherapy of Tuberculosis, 541
Kennedy, Dr. J. S. : Benefits to Aphids from Feeding on Galled and Virus-infected Leaves, 825
  A Biological Approach to Plant Viruses, 890
Kennedy, Dr. R. A. : Appointed senior scientific officer (physiologist), Heat Research Unit, Nigeria, 147
Kent, Dr. Andrew (edited by) : An Eighteenth Century Lectureship in Chemistry, *review* by L. F. Gilbert, 969
Kepler, Johannes : Life and Letters (Carola Baumgardt), *review* by Sir H. Spencer Jones, 483
Kerr, Sir James Graham : A Naturalist in the Gran Chaco, *review* by Prof. James Ritchie, 260
  Obituary of Prof. W. E. Agar, 494
Kerr, Peter : Honorary fellowship of Heriot-Watt College, Edinburgh, conferred on, 146
Kerr, Dr. Ralph W. (edited by) : Chemistry and Industry of Starch, second edition, *review* by Prof. R. H. Hopkins, 179
Kerrison, Colonel A. V. : Appointed a chief scientific officer in the Royal Naval Scientific Service, 1025 ; work of, 1025
Kertesz, A. : Appointed pathologist, Nigeria, 147
Kertész, Dr. Denis : Tyrosinase and Polyphenoloxidase—the Role of Metallic Ions in Melanogenesis, 697
Kettlewell, R. W. : Appointed director of agriculture, Nyasaland, 641
Keynes, Dr. Geoffrey : John Ray, a Bibliography, *review* by Dr. W. T. Calman, 352
Keynes, R. D. : Radiochemical Techniques in Analysis, 154
Keyworth, Dr. W. G. : Awarded a Leverhulme Research Grant, 19
Khalifa, A. A., and Salah, Prof. M. K. : Spectrophotometric Determination of Hæmoglobin in Blood, 915
Khastgir, Dr. S. R., and others : Volume Rectification in Zincite, 162
Kidd, John (1775–1851), 454
Kiely, D. G. : Awarded an extra Ambrose Fleming Premium of the Institution of Electrical Engineers, 103
Kilburn, Dr. T. : The New Universal Digital Computing Machine at the University of Manchester, 95
Kilkenny, B. C. : Awarded an *Endeavour* First Prize, 274
Killick, A. B. : Appointed professor of agriculture and director of studies at the Imperial College of Tropical Agriculture, 234, 638, 641 ; work of, 234, 638
Kilvington, T., and others : The London–Birmingham Television-Cable System, 1034
Kimura, Prof. Kenjiro : *Obituary* of Dr. Yoshio Nishina, 453
Kimura, Mutsuo, and others : Paper Partition Chromatography of Alcohols using the Potassium Xanthogenates, 511
Kinematograph Society, British (Scientific and Technical Group of the Royal Photographic Society and the) : Symposium on Chemical Shortages and the Efficient Use of Processing Solutions, 103
King, Prof. E. J., and Ventura, S. : Light Filters of Coloured 'Perspex', 702
King, F. C. : The Weed Problem, *review* by Prof. R. H. Stoughton, 715
King, Henry R. : Honorary fellowship of Heriot-Watt College, Edinburgh, conferred on, 146
King, Prof. W. B. R. : Geology and Military Strategy, 226
King's College, London : Appointment of J. K. T. L. Nash to the University of London readership in civil engineering, 146
  Title of professor emeritus of philosophy in the University of London conferred on Prof. H. F. Hallett, 147
  Grant of £10,000 from the Nuffield Foundation for research in biophysics, 454
King's College, Newcastle-upon-Tyne : Stephenson Building opened by H.R.H. the Duke of Edinburgh, 1069
Kinnear, Sir Norman : Isabelline Shrike on the Isle of May, 939
Klein, Otto (designed by) : Warne's Metric Conversion Tables, *review*, 136
Klement, Dr. O. : Theoretical Determination of Electron Density in Organic Molecules, 162
Klerk, J. de : Effect of a Magnetic Field on the Propagation of Sound Waves in a Ferromagnetic Material, 963
Klineberg, Otto : Race and Psychology, 862
Klopsteg, Dr. Paul E. : Appointed assistant director of the National Science Foundation for the Division of Physical, Mathematical and Engineering Sciences, 724 ; work of, 724
Klyne, Dr. W. : Pregnan-7-ol and Pregnan-12-ol, 835
Knapp, D. R., and Mitra, Dr. R. P. : Electron Diffraction by Clay Minerals with a Fibrous or Rod-like Habit, 380
Knaysi, Prof. Georges : Elements of Bacterial Cytology, second edition, *review* by Dr. K. A. Bisset, 439
Knight, Prof. A. Rex : Current Trends in General Psychology, 866
Knight, B. C. : Awarded a Postgraduate Agricultural Scholarship by the Ministry of Agriculture and Fisheries, 683
Knight, Prof. F. H. : Honorary degree of LL.D. of the University of Glasgow conferred on, 156
Knight, R. : Appointed plant breeder, West African Cocoa Research Institute, Gold Coast, 641
Knight, S. G. (Ehrlich, H. L., and) : Glucose and Lysogenesis in *Bacillus megatherium*, 658
Knox, Dr. W. E., and others : Intermediary Metabolism of Tryptophan, 20
Kodicek, Dr. E., and Reddi, K. K. : Paper Chromatography of Nicotinic Acid Derivatives, 475
Koehler, Prof. O. : Ability of Birds to Count, 373
Kofler, M., and others : Pure *All-trans* Vitamin A Acetate and the Assessment of Vitamin A Potency by Spectrophotometry, 598
Kompfner, R. : Awarded a Heinrich Hertz Premium of the British Institution of Radio Engineers, 413
Kon, Prof. G. A. R. : The Chemistry of Cell Division, 463
Kon, Dr. S. K., and others : Mode of Action of Antibiotics in Stimulating Growth of Chicks, 332
Konishi, C., and others : Effect of Nitrogen-fixing Blue-Green Algæ on the Growth of Rice Plants, 748
Koopmans, Tjalling C. (edited by) : Statistical Inference in Dynamic Economic Models, *review*, 620
Kopal, Dr. Zdenek : Appointed to the chair of astronomy at the University of Manchester, 234 ; work of, 234
Korkes, Dr. Seymour (Strecker, Prof. Harold J., and) : Reversible Oxidation of Glucose by Glucose Dehydrogenase, 913
Kornberg, H. L. : Awarded the John Stokes Research Fellowship of the University of Sheffield, 726
Korosy, Dr. F., and Székely, Gy. : Positive Bromine Ions I, 77
Kosack, H. P. : New Map of the Antarctic, 275
Kow, Tham Ah : The Food and Feeding Relationships of the Fishes of Singapore Straits, 640
Krabbe, Dr. U. : Awarded a Montefiore Prize for Electrical Development, 413
Kramers, Prof. H. A. : Elected an honorary fellow of the Royal Society of Edinburgh, 61
  Mixing and Agitating in Liquid Media, 376
  Awarded the Hughes Medal for 1951 by the Royal Society, 856, 1018
Kreger, D. R., and others : Composition and Structure of Yeast Cell Walls, 693
Krige, C. J. MacK. : Appointed chief agricultural officer, Northern Rhodesia, 276
Krishna Iyengar, Dr. C. V. : Intraseasonal Growth Variation and Cultivation of Sugar-cane, 252
Krishna Iyer, Prof. P. V., and Rao, A. S. Prakash : Runs in a Sequence of Observations, 557 ; *erratum*, 770
Krishnamurti, Prof. K., and Kate, S. R. : Changes in Electrical Conductivity during Bacterial Growth, 170
Krishnan, Sir K. S., and Roy, Dr. S. K. : Elastic Constants of Alkali Halide Crystals, 869, 983
Krishnan, P. S. : Apyrases of Moulds, 171
Kristiansson, Krister (Friesen, Prof. Sten von, and) : Measurements of Mass Ratios in Nuclear Emulsions, 377
Kruyt, Prof. H. R. : Honorary degree of LL.D. of the University of Glasgow conferred on, 156
Kruyt, Prof. H. R. (edited by) : Colloid Science, Vol. 2, *review* by Dr. A. S. C. Lawrence, 800
Kurtze, G. (Tamm, K., and) : Absorption of Sound in Aqueous Solutions of Electrolytes, 346
Kutschke, Dr. K. O. G. : Awarded a Ramsay Memorial Fellowship for chemical research, 983
Kuyper, B. (Wesley, A., and) : Electron-Microscopic Observations on the Xylem Elements of a Fossil Plant, 137
Kvifte, G. : Atmospheric Oxygen Bands in Emission from Neon–Oxygen Mixtures, and in Night Sky and Auroral Luminescences, 741

LA ROCHE, Charles (Edwards, Prof. Ronald S., and): Industrial Research in Switzerland, *review* by R. Brightman, 398
Lackey, C. H. W. : Awarded a Sebastian de Ferranti Premium of the Institution of Electrical Engineers, 103
Lacy, E. D. : Minerals and Magmas—Studies at High Temperatures and Pressures, 537
Lagermalm, Gosta, and others : Occurrence of Thin Membranes in the Surface Layers of Human Skin and in Finger Nails, 1080
Laing, J., and Blakemore, F. : Erythrocyte Antibodies as a Cause of Abortion in Cattle, 656
Laird, A. J. : Current Trends in General Psychology, 866
Laird, Dr. M. : Blood Parasites of Mammals in New Zealand, 640
  A Contribution to the Study of Fijian Hæmatozoa, 640
Laird, Sir Patrick : Problems of Marginal Land Farming, 457
Lakshminarayan Rao, M. V. (Sahasrabudhe, M. R., and) : Effect of Vitamin B_{12} on the Synthesis of Protein and Nucleic Acids in the Liver, 605
Lamb, Commissioner David : *Death of*, 144
Lamb, I. Mackenzie : Biochemistry in the Taxonomy of Lichens, 38
Lambert, J. L. M. : Appointed geologist (petrologist), Tanganyika, 983
Lambert, Miss J. M. : Awarded a Leverhulme Research Grant, 19
Lamerton, Dr. L. F. : Applications of Physics in the Diagnosis and Treatment of Cancer, 1024
Lamont, Dr. H. G. : Appointed to the chair of comparative pathology at Queen's University, Belfast, 1104 ; work of, 1104
Lamont, N. : Appointed economic botanist, Fiji, 147
Lander, Dr. P. E. : The Feeding of Farm Animals in India, *review* by Dr. John Hammond, 440
Landskroner, K. : Appointed an agricultural officer, Gold Coast, 641
Lane, J. T. D. : Chemotherapy of Tuberculosis, 541
Lang, A. R. : The Proportional Counter in X-Ray Diffraction Work, 907
Lang, David A. (Proctor, Prof. Bernard E., and) : Vitamin B_{12} Content of Soft- and Hard-shell Clams, 36 ; *erratum*, 63
Lang, Dr. H. R. : The World of Science, *review*, 532
Lang, Dr. H. R. (edited by) : British Journal of Applied Physics, Vol. 1, 1950, *review* by S. Weintroub, 7
Langdon-Davies, John : Jubilee Book of the National Physical Laboratory, 410
Langenhop, C. E., and others : Contributions to the Theory of Nonlinear Oscillations (edited by S. Lefschetz), *review* by Prof. H. T. H. Piaggio, 49
Lapage, Dr. G. : Indian Veterinary Research Institute—Diamond Jubilee Celebrations, 287
Laporte, Prof. M. : High-Power Photo-Flash Tubes, 552
Laptain, Miss J. M. : Awarded a Nature Conservancy research studentship for postgraduate training in ecology, 984
Larin, Dr. N. M. : Preparation of the Specific Purified Antigen of Canine Hepatitis Virus and Antiserum for Serological Studies, 745
Larin, Dr. N. M., and others : Cultivation of Canine Hepatitis Virus in Embryonated Hen's Eggs and its subsequent Transmission to Dogs, 699
Larralde, J. (Ponz, Prof. F., and) : Effect of Phosphates and the *p*H on Sugar Absorption, 912
Lasnitzki, I. : Freezing and Drying, 852
Latham, P. R. : Awarded a Postgraduate Agricultural Scholarship by the Ministry of Agriculture and Fisheries, 683
Latham, R. W. : People at Work, 988
Latus, M., and others : Chlorophyll Inhibition and Growth Regulation by several Tetronic Acid Derivatives, 85
Laudelout, H., and Meyer, J. : Temperature Characteristics of the Microflora of Central African Soils, 791

Laughton, Dr. Nancy : Fertility, 286
Lauritsen, C. C. : Elected president of the American Physical Society, 156
Laver, F. J. M., and others : The London–Birmingham Television-Cable System, 1034
Lavoisier : Correspondence of (Dr. Douglas McKie), 63
Law, A. B. : Appointed meteorological officer, Northern Rhodesia, 147, 641
Law, H. B. : *Recent Developments and Techniques in the Maintenance of Standards*, 596
Lawden, D. : Automatic Control, 405
Lawford, Comdr. A. L., and others : Variations in Brood-Strength in the North Sea Haddock, in the Light of Relevant Wind Conditions, 317
Lawrence, Dr. A. S. C. : Colloid Science, *review*, 800
Lawrence, Prof. E. O. : Honorary degree of LL.D. of the University of Glasgow conferred on, 156
Lawrence, S. M., and others : An Improved Diluent for the Production of African Horse-sickness Virus Vaccine, 655
Lawrence, William J. C. : Science and the Glasshouse, second edition, review by Wilfred Corbett, 397
Lawrie, J. J. : Appointed *assistant conservator of forests*, Somaliland Protectorate, 368
Lawson, J. D. : Degree of Ph.D. of the University of Aberdeen conferred on, 103
  Appointed research fellow in geology at the University of Birmingham, 940
Layne, Dr. D. A. : Applications of Physics in the Diagnosis and Treatment of Cancer, 1023
Layton, J. M. : Automatic Control, 405
Le Poole, J. B. : Technique of Electron Microscopy, 819, 820
Lee, C. A. : Appointed director, Meteorological Services, Federation of Malaya, 641
Lee, S. H. (Hansen, R. S., and) : Reaction between Glucose and the Terminal Amino Group of Lysine, 744
Learmonth, Sir James : Appointed a member of the Medical Research Council, 413
Lecky, J. A., and others : Adsorption of Water and Methanol on Coal, 124
Lederberg, J. : Genes and Mutations, 733
Lederer, Dr. E. : Chemotherapy of Tuberculosis, 539, 540
Leedal, G. P. : Appointed geologist, Tanganyika, 368
Lees, Dr. A. D. : Insect Physiology in relation to Applied Biology, 973
Lees, Dr. H. : The Chemistry of the Nitrifying Bacteria, 730
Leeson, Colonel B. H. : The Education and Training of the Engineer, 15
Leeuwenhoek, Antoni van : Zijn Leven en zijn Werken (Dr. A. Schierbeek), Deel 1 and Deel 2, *review* by Prof. F. J. Cole, 927
Lefschetz, S. : L'Analysis situs et la géométrie algébrique, *review*, 717
Lefschetz, S. (*edited by*) : *Contributions to the Theory of Nonlinear Oscillations* (S. P. Diliberto, L. L. Rauch, F. H. Brownell, M. L. Cartwright, J. G. Wendel, C. E. Langenhop, A. B. Farnell, W. Wasow), *review* by Prof. H. T. H. Piaggio, 49
Leighton, —, and Brown, Guthrie : Ports, Harbours and Dry Docks, 239
Leiris, H. de : Stress Analysis, 735
Lemaitre, Canon Georges : The Primeval Atom, translated by Betty H. and Serge A. Korff, *review by Prof. T. G. Cowling*, 259
  L'Univers, *review* by Prof. T. G. Cowling, 259
Leone, Dr. E., and Mann, Dr. T. : Ergothioneine in the Seminal Vesicle Secretion, 205
Leslie, Miss M. S. : Degree of D.Sc. of the University of London conferred on, 770
Leubuscher, Charlotte : The Processing of Colonial Raw Materials, 1105
Levan, A. : Genes and Mutations, 732
Levi, Dr. A. A., and others : A Metabolite of 'Paludrine' with High Anti-malarial Activity, 1080
Levi, Dr. I., and Purves, Prof. C. B. : The Structure and Configuration of Sucrose, 103
Levisohn, Ida (Jones, Prof. W. Neilson, and) : Acid Tolerance in Plants, 791
Levy, E. Bruce : Awarded the R. B. Bennett Empire Prize for 1951 by the Royal Society of Arts, 456
Lewis, B. (Street, Dr. R., and) : Anomalous Variation of Young's Modulus of Antiferromagnetics at the Néel Point, 1036
Lewis, Brigadier Sir Clinton, and Campbell, Colonel J. D. (edited by) : The Oxford Atlas, *review*, 1016
Lewis, E. R. : *Genes and Mutations*, 732
Lewis, G. L. : Theology of Films and Surfaces, 945
Lewis, Marion, and others : A Further Example of *Kidd* (*Jkb*) Haemagglutinin, 790
Leyburn, H. : Awarded a Sebastian de Ferranti Premium of the Institution of Electrical Engineers, 103
Leycester, J. H. : Storage of Farm Products, 489
L'Héritier, P. : *Genes and Mutations*, 733
Library Association : Reader's Guides, New Series, No. 9, Chemical Technology, 103
  Annual Conference of the, 329
  The Subject Index to Periodicals, 1949, *review*, 486
  Report on the Municipal Library System of London and the Home Counties (edited by James D. Stewart), 500
Lickley, Prof. R. L. : *The Education and Training of the Engineer*, 15
Liebmann, Dr. G. : German Society for Electron Microscopy—Third Annual Conference, 70
Liebmann, Dr. G. (Drummond, Dr. D. G., and) : Technique of Electron Microscopy, 819
Lindberg, Joel, and others : Occurrence of Thin Membranes in the Surface Layers of Human Skin and in Finger Nails, 1080
Lindegren, *Prof. Carl C. (Hestrin, Prof. Shlomo, and)* : *Gene Function in the Homologous and Heterologous Induction of α-Glucosidases in Yeast by α-Glucosides*, 913
Linder, C. T. : The Measurement of Low Temperatures, 411
Lindley, Sir Frank : *Obituary*, 453
Lindsay, Dr. E. M. : Report for 1950 on Armagh Observatory, 504
Linehan, Dr. P. A. : Appointed to the chair of agricultural botany at Queen's University, Belfast, 1104 ; *work of*, 1104
Linell, Dr. F. (Nordén, Dr. A., and) : A New Type of Pathogenic *Mycobacterium*, 826
Lines, Dr. A. W. : Awarded an extra Ambrose Fleming Premium of the Institution of Electrical Engineers, 103
Lines, G. W. : Appointed director of agriculture, Sierra Leone, 189
Linker, Alfred, and others : Isolation of a Crystalline Disaccharide, Hyalobiuronic Acid, from Hyaluronic Acid, 996
Linstead, Prof. R. P. : Thorpe's *Dictionary of Applied Chemistry*, Vol. 10, fourth edition, *review*, 716
Linstead, Prof. R. P., and others : Chemistry of the Oxidative Metabolism of certain Aromatic Compounds by Micro-organisms, 772
Lipson, Dr. H. : International Union of Crystallography—Congress at *Stockholm*, 501
  Aspects of X-Ray Crystallography, *review*, 576
Lipson, Dr. H., and others : *Fourier Synthesis by Optical Interference*, 160
Lissett, R. N. : Appointed senior surveyor, Uganda, 189
Liverpool Observatory and Tidal Institute : Annual Report for 1950, 184
Lloyd, R. G. : Law of Copyright and Industrial Designs, *review*, 847
  Introduction to the Patenting of Inventions, *review*, 973
Local Government and Planning, Minister of : *Progress Report* on the Work of the Ministry of Town and Country Planning, 45
Lockemann, Prof. Dr. Georg : Geschichte der Chemie in kurzgefasster Darstellung, Band 1, *review* by J. R. P., 716
Locket, G. H., and Millidge, Dr. A. F. : British Spiders, Vol. 1, *review* by T. H. Savory, 714
Lockie, J. D. : Awarded a Nature Conservancy research studentship for postgraduate training in ecology, 984
Lockspeiser, Sir Ben : Automatic Control, 404
  World Communications—The Impact of Speed, 446
  Recent Developments and Techniques in the Maintenance of Standards, 594
Lockwood, J. F. : Appointed a member of the National Research Development Corporation, 545
London, Fritz : Superfluids, Vol. 1, Macroscopic Theory of Superconductivity, *review* by Dr. K. Mendelssohn, 670
London Brick Co., Ltd. : Opening of new Research Laboratories, 831
London County Council : Christmas Lectures, 984
London Hospital Medical College : Appointment of Dr. R. J. Harrison as *head of the Department of Anatomy*, with the title of University of London reader in anatomy, 683
London School of Economics and Political Science : Appointment of T. W. Hutchison and R. Turvey to University of London readerships in economics, 368
London School of Hygiene and Tropical Medicine : Title of professor emeritus of chemistry as applied to hygiene in the University of London *conferred on Prof. M. E. Delafield*, 147
  Langley Memorial Prize awarded to Dr. J. H. Gerber, 899
Long, Dr. Joyce R. : Labour Turnover under Full Employment, 993
Long, W. M. (Bronowski, Dr. J., and) : Statistical Methods in Anthropology, 794
Long Ashton Research Station : Field Day (R. W. Marsh), 375
Loofbourow, Dr. John R. : *Death of*, 366
Lora Tamayo, *Prof. M.*, and Municio, A. M. : *Coenzyme of Kidney Phosphatase*, 249
Lord, Dr. K. A. : Insect Physiology in relation to Applied *Biology*, 974
Lothian, G. F. : Blue Sun and Moon, 1086
Lofty, Miss Tooraya : Chromosome Number and Chromosome Morphology in *Helicophyllum crassipes*, 338
Loudon, J. : Appointed lecturer in engineering production at the University of Glasgow, 1068
Loudon, Dr. James D. : Chemistry of Heterocyclic Compounds, *review*, 618
Lourie, Dr. E. M. : The Evaluation of Chemotherapeutic Substances, 865
Lousley, J. E. : Recent Research and Additions to the British Flora, 934
Lovell, Dr. A. C. B. : Appointed to the newly created chair of radio-astronomy at the University of Manchester, 17 ; work of, 17
Lowenstein, Dr. O. E. : Appointed Mason professor of zoology in the University of Birmingham, 940, 981 ; work of, 981
Lowson, William : *Death of*, 144
Lucas, D. H. : Awarded a Mather Premium of the Institution of Electrical Engineers, 103
Luce, Dr. A. A. (*edited by*) : *The Works of George Berkeley, Bishop of* Cloyne, Vol. 4, *review* by Prof. A. D. Ritchie, 1014
Luck, Prof. J. Murray, and others : Composition of Histone prepared from Rat Liver Desoxypentosenucleoprotein, 82
Ludlam, F. H. : Natural and Artificial Production of Atmospheric Precipitation, 533
Lumsden, Dr. C. E. : Appointed second Henry Head Research Fellow of the Royal Society, 144
Luomala, Katharine : The Menehune of Polynesia and other Mythical Little People of Oceania, 639
Luria, S. E. : Genes and Mutations, 733
Luscombe, G. W. : Awarded an Ambrose Fleming Premium of the Institution of *Electrical Engineers*, 103
Luyet, B. J. : Freezing and Drying, 852
Lynn, C. W. : Appointed *assistant director of agriculture, Gold Coast*, 983
Lyon, A. G. (Howard, H. W., and) : Effect of Light on the Germination of Watercress Seeds, 253
Lyons, L. E. : Awarded a Ramsay Memorial Fellowship for chemical research, 983

MABBITT, L. A. : Chemistry and Bacteriology of Silage, 731
McAdam, Dr. W., and others : Psychological and Biochemical Effects of Lysergic Acid Diethylamide, 827
Macbeath, Dr. A. M. : *Appointed lecturer in mathematics at the University* College of North Staffordshire, 19
Maccabaeans, Society of : Meldola Medal, 545
McCance, Sir Andrew : Metals and Alloys, 414
McCance, Prof. R. A. (Glaser, Prof. E. M., and) : Life and Work in Extreme Environmental Conditions, 363
McCance, Prof. R. A., and others : Cholinesterase Activity in the Secretions *of the Pancreas of the Dog and Parotid of the Pig*, 788
McCartney, Dr. W. : Odours of Minerals, 274
McClintock, B. : Genes and Mutations, 732
McClure, T. J. (Filmer, Daisy B., and) : Absorption of Anti-Nematode Antibodies from Ewe's Colostrum by the New-born Lamb, 170
MacColl, J. E. : Management Problems and Local Government, 553

Science Museum, London : The 1951 Exhibition of Science (G. R. Noakes), 69
Exhibition of Agricultural Machinery, 145
Scientific Civil Service : Promotion of individual research workers, 497
Scientific Film Association, International : Fifth Congress, 276
Scientific Policy, Advisory Council for : Fourth Annual Report (1950–1951), 491
Scientific Societies, South-Eastern Union of : Annual Congress, 25
Scientific Unions, International Council of : Annual Meeting, 938
Scientific Workers, Association of : Appointment of Ben Smith as general secretary, 770
Scientific Workers, Association of (Cambridge Branch) : Conference on the Ethical Problems of the Scientific Worker, 1112
Scientific and Industrial Research, Advisory Council for : Appointment of Sir Eric Rideal as a member, 545
Scientific and Industrial Research, Department of : Conference on Automatic Control, 404
'Open Days' at the Chemical Research Laboratory, 63, 413, 723
Brief Guide to the Research Activities of the D.S.I.R. and the Research Associations, 455
Appointment of Dr. D. G. Sopwith as director of mechanical engineering research, 769
Report of the Mechanical Engineering Research Board for 1947–1950, 779
International Symposium on the Organization of Scientific and Industrial Research, 814
Scientific and Industrial Research, Department of (Technical Information and Documents Unit) : Microfilm of the I. G. Farben Central Laboratory Index, [illegible]
Scientific Research, Department of, India : Report for 1950–51, 419
Scorgie, Prof. N. J. : Title of professor of veterinary hygiene in the University of London conferred on, 236
Scott, A. E. (Westman, Dr. A. E. R., and) : Chromatographic Evidence for the Tetraphosphate Ion, 740
Scott, Dr. W. N. : Appointed senior agricultural officer, Federation of Malaya, 641
Scott, Dr. J. R. : *Obituary* of Dr. D. F. Twiss, 100
Scott, Richard (Taylor, Duncan, and) : Solid Phase Determinations in the System Aluminium Sulphate/Sulphuric Acid/Water using Tracer Technique, 520
Scott, W. N. : Appointed veterinary officer, Uganda, 641
Scottish Advisory Council : First Report of the Scottish Hill Farm Research Committee, 187
Scottish Hill Farm Research Committee : First Report, 187
Seaborg, Prof. G. T. (McMillan, Prof. E. M., and) : Awarded jointly the Nobel Prize for Chemistry for 1951, 897
Sears, —. : The Application of Statistical Methods to Chemistry, 1073
Seelich, Dr. F., and Hübl, P. : Effect of Histamine on the Activity of Hyaluronidase, 1125
Sekiguti, Prof. Rikiti : *Death of*, 856 ; *obituary* by Prof. Y. Hagihara, 1063
Seligman, G. : Elected president of the British Glaciological Society for 1952, 1027
Seligman, Dr. Richard : To receive the first award of the Dairy Technology Gold Medal of the Society of Dairy Technology, 321
Selwyn, Dr. E. W. H. : Photography in Astronomy, *review* by L. V. Chilton, 485
Selye, Prof. Hans : An Extra-Adrenal Action of Adrenotropic Hormone, 149
Sen Gupta, G. C. : Effect of Hosts on the Egg Coloration of the Parasite *Bracon gelechiae* Ashmead (Braconidae), 793
Sen Sarma, P. (Mukerji, D., and) : Spermatheca in Sucking Louse, 612
Senior, —. : The Application of Statistical Methods to Chemistry, 1074
Serventy, D. L., and Whittell, H. M. : A Handbook of the Birds of Western Australia (with the exception of the Kimberley Division), second edition, *review* by Dr. A. J. Marshall, 441
Seth-Smith, David : Man's Control of Wild Animals, 26
Natural History—Birds and Mammals, *review* by M. A. C. Hinton, 136
Shackle, Dr. G. L. S. : Appointed to the Brunner chair of economic science at the University of Liverpool, 19
Shakespear, Dr. G. A. : *Obituary*, 496
Shamos, Prof. Morris H., and Roth, Prof. Sidney G. (edited by) : Industrial and Safety Problems of Nuclear Technology, *review* by Sir John Cockcroft, 263
Sharma, P. Ch. (Williams, Dr. W. T., and) : Urease Metabolism in *Citrullus*, 659
Sharpe, J. : Awarded an extra Mather Premium of the Institution of Electrical Engineers, 103
Shaw, J. C. : Awarded a Student's Premium of the Institution of Electrical Engineers, 103
Shaw, J. C. S. : Some Aspects of Discharge Physics, 141
Shaw, J. T. B., and Smith, Dr. S. G. : Amino-acids of Silk Sericin, 745
Shearer, Roderick M. : Honorary fellowship of Heriot-Watt College, Edinburgh, conferred on, 146
Shelley, I. J. : Awarded a Student's Premium of the Institution of Electrical Engineers, 103
Shepheard, R. B. : Ships Structures—a Century of Progress, 415
Shepherd, A. A. : Appointed an assistant lecturer in physics at the University College of North Staffordshire, 19
Shepherd, Dr. W. C. F. : Appointed an honorary lecturer in mining at the University of Sheffield, 726
Sherborne, J. W. (Cottle, Basil, and) : The Life of a University, *review*, 848
Sheridan, M. J. : Awarded an Endeavour Special Prize, 274
Sherif, I. L. (Gregory, Prof. H. S., and) : A New Method for Measuring the Atomic Heats of Gases, 1123
Sherwell, J. : Awarded a Postgraduate Agricultural Scholarship by the Ministry of Agriculture and Fisheries, 683
Shewan, Dr. James : Bacteriology of Marine Fish, 730
Shibata, Prof. Shoji (Asahina, Prof. Yasuhiko, and) : Chemistry of Lichen Substances, *review* by Dr. J. C. Deere, 889
Shillam, K. W. G. : Awarded a Postgraduate Agricultural Scholarship by the Ministry of Agriculture and Fisheries, 683
Shipp, G. C. : Mixing and Agitating in Liquid Media, 376
Shome, Dr. S. C. : Awarded a National Institute of Sciences of India Senior Research Fellowship, 498
Shooter, K. V. : Rheology of Films and Surfaces, 945
Shorland, Dr. F. B., and Johannesson, Miss D. L. : C_{20-22} Unsaturated Acids of Butterfat, 75 ; *erratum*, 899
Short, L. N., and others : Raman and Infra-Red Spectra of Germanium Tetrafluoride, 557
Sidgwick, Prof. N. V. : Elected an honorary life member of the Faraday Society, 276
Sierpinski, Prof. Waclaw : Lecons sur les nombres transfinis, nouveau tirage, *review*, 758
Sikorski, J. : Technique of Electron Microscopy, 820
Silas, E. G. : Awarded a National Institute of Sciences of India Junior Research Fellowship, 498
Siliprandi, Dr. D., and Siliprandi, N. : Cocarboxylase in Experimental Diabetes, 422

United States National Bureau of Standards : Resignation of Dr. E. U. Condon as director, 276

United States National Museum : Annual Report for 1949–50, 899

United States Navy : Appointment of Dr. Robert F. Rushmer as superintendent of the Scientific Department at the Aviation Medical Acceleration Laboratory of the, 60

Universities of the British Commonwealth, Association of : Report of Proceedings at the 1950 Conference of Home Universities, 18

Universities of Great Britain and Northern Ireland : Conference, 984

Universities' Federation for Animal Welfare—Silver Jubilee (Prof. A. N. Worden), 109

University of Aberdeen : Degree of Ph.D. conferred on W. C. Bain, Miss M. I. Chalmers, T. L. Dodsworth, Miss G. M. Ellinger, K. El Shazly, O. C. Farquhar, E. A. Fitzpatrick, D. A. Jones, J. D. Lawson, F. H. C. Marriott, P. A. Orkin, W. Paul and E. A. D. White, 103

Honorary degree of LL.D. conferred on Sir William Ogg, 147

University of Adelaide : Appointment of Dr. D. G. Catcheside to the chair of genetics at the Waite Agricultural Research Institute, 234

Appointment of F. B. Bull to the chair of civil engineering, 1066

University of Birmingham : Introduction to a University, 18

Honorary degree of D.Sc. conferred on Sir James Chadwick, Sir Robert Davis and Sir John Simonsen, 19

Twenty-first Annual Report of the Joint Standing Committee for Research, 62

Retirement of Prof. W. Stiles from the Mason professorship of botany, 497

Appointment of Dr. E. J. Maskell to the Mason chair of botany, 497

Appointment of P. J. Palmer as lecturer in civil engineering, 682

Appointment of J. H. O. Varley as lecturer in metallurgy, 682

Resignation of Dr. E. W. Twyman as lecturer in botany, 682

Resignation of W. S. Norman as lecturer in chemical engineering, 682

Resignation of Dr. A. J. Wilson as lecturer in mechanical engineering, 682

Resignation of Dr. Mary Gregg as lecturer in botany, 682

Resignation of Dr. Vera Norris as senior statistical officer in the Department of Medical Statistics, 682

  Appointment of Dr. O. E. Lowenstein as Mason professor of zoology, 940, 981
  Appointment of Dr. H. R. Mulholland as lecturer in mathematics, 940
  Appointment of Dr. C. E. Harrold as lecturer in botany, 940
  Appointment of Dr. F. J. Wallace as lecturer in mechanical engineering, 940
  Appointment of W. M. Crooks and D. C. Freshwater as lecturers in chemical engineering, 940
  Appointment of Dr. J. M. Rushforth as research fellow in mathematics, 940
  Appointment of J. D. Lawson as research fellow in geology, 940
  Appointment of Dr. A. R. Harding and T. Broom as research fellows in metallurgy, 940
  Title of reader in thermodynamics conferred on Dr. F. K. Bannister, 940
  Resignation of Dr. R. T. W. Hall as lecturer in chemical engineering, 940
  Studies in Economics and Society, Monograph A.2 (Labour Turnover under Full Employment, by Dr. Joyce R. Long), and Monograph A.3 (Absence under Full Employment, by Hilde Behrend), 993
University of Bristol : Foundation stone of the new Engineering School building laid by Winston S. Churchill, 1066
University of California : Endowment of the M. Theodore Kearney Foundation of Soil Science in the College of Agriculture, 938
University of California, and others : Second Conference on Coastal Engineering, 456
University of Cambridge : Adams Prize for 1949–50 awarded jointly to Dr. G. K. Batchelor, W. R. Dean and Dr. L. Howarth, 19
  Grant of £25,000 from the Nuffield Foundation to the Mathematical Laboratory, 367
  Grant of £5,000 from the Nuffield Foundation to the Chemical Laboratory, 367
University of Edinburgh : Appointment of Dr. M. L. Anderson to the chair of forestry, 812
  Retirement of Sir Godfrey Thomson from the chair of education, 812
  Appointment of Prof. J. G. Pilley to the chair of education, 812
University of Genoa (Geophysical Institute) : Conference on Maritime Meteorology, 102
University of Glasgow : Fifth Centenary Celebrations (J. B. Neilson), 155
  Appointment of A. W. Babister as lecturer in aeronautical engineering, 1068
  Appointment of S. A. Barrett as lecturer in zoology, 1068
  Appointment of E. H. Bellamy, W. K. Burton, A. L. Cockcroft and J. G. Rutherglen as lecturers in natural philosophy, 1068
  Appointment of W. A. Donaldson, J. Hunter and A. P. Robertson as lecturers in mathematics, 1068
  Appointment of A. B. Garven and J. E. Gibson as lecturers in civil engineering, 1068
  Appointment of J. S. S. Inglis as lecturer in animal husbandry, 1068
  Appointment of S. Jennings as lecturer in veterinary surgery, 1068
  Appointment of J. Loudon as lecturer in engineering production, 1068
  Appointment of I. M. McIntyre as lecturer in veterinary medicine and surgery, 1068
  Appointment of H. A. Moisley as lecturer in geography, 1068
  Appointment of W. Mulligan as lecturer in veterinary biochemistry, 1068
  Appointment of R. S. Patrick as lecturer in pathology, 1068
  Appointment of R. Ogilvie MacKenna as librarian and keeper of the Hunterian Books and MSS., 1068
  Appointment of Group-Captain W. K. Stewart as honorary lecturer in aviation physiology, 1068
  Resignation of John B. Birks as a lecturer in natural philosophy, 1068
University of Houston (Rice Institute of the), and others : Second Conference on Coastal Engineering, 456
University of Illinois Engineering Experiment Station : Circular Series No. 62, Preparing Technical Material for Publication, 857
University of Leeds : Appointment of Dr. R. P. Hullin as lecturer in biochemistry, 147
  Appointment of W. S. Reith as research chemist and honorary lecturer in the Department of Botany, 147
  Title of emeritus professor of physics conferred to Prof. R. Whiddington, 726
  Appointment of Dr. J. G. Wilson to the second chair of physics, 726, 856
  Appointment of R. L. Holmes as lecturer in anatomy, 726
  Appointment of G. A. Mogey as lecturer in pharmacology, 726
  Appointment of K. G. Towers as veterinary officer and lecturer in veterinary hygiene, 726
  Appointment of Dr. F. K. Sutcliffe as research lecturer in the Department of Colour Chemistry and Dyeing, 726
  Appointment of Dr. R. Reed as a lecturer in the Department of Leather Industries, 726
  Appointment of J. C. Macrae as lecturer in gas chemistry in the Department of Coal, Gas and Fuel Industries, 1027
University of Liverpool : Appointment of Dr. G. L. S. Shackle to the Brunner chair of economic science, 19
  Appointment of Dr. Andrew Wilson as professor of pharmacology, 236
University of London : Appointment of Dr. Bernhard Katz to the University chair of biophysics at University College, 18
  Title of professor of applied mechanics in the University conferred on Dr. Hugh Ford, 18
  Title of professor of technical optics in the University conferred on Dr. W. D. Wright, 18
  Title of professor of veterinary physiology in the University conferred on Dr. E. C. Amoroso, 18
  Title of professor of veterinary pathology in the University conferred on T. J. Bosworth, 18
  Appointment of Dr. K. A. Hirsch to the University readership in mathematics at Queen Mary College, 146
  Appointment of J. K. T. L. Nash to the University readership in civil engineering at King's College, 146
  Appointment of Dr. Stanley Rowlands to the University readership in physics at St. Mary's Hospital Medical School, 146
  Title of professor emeritus of chemistry as applied to hygiene in the University conferred on Prof. M. E. Delafield, 147
  Title of professor emeritus of philosophy in the University conferred on Prof. H. F. Hallett, 147
  Title of professor emeritus of anatomy in the University conferred on Prof. M. F. Lucas Keene, 147
  Title of professor emeritus of chemistry in the University conferred on Prof. J. R. Partington, 147, 319
  Title of professor emeritus of physiology in the University conferred on Prof. A. V. Hill, 147
  Title of professor emeritus of zoology and comparative anatomy in the University conferred on Prof. D. M. S. Watson, 147
  Title of professor emeritus of chemical engineering in the University conferred on Prof. H. E. Watson, 147
  Degree of D.Sc. conferred on W. B. Mann, 147
  Degree of D.Sc.(Econ.) conferred on R. H. Coase, 147
  Title of professor of veterinary medicine in the University conferred on Prof. H. Burrow, 236
  Title of professor of veterinary hygiene in the University conferred on Prof. N. J. Scorgie, 236
  Title of reader in inorganic chemistry in the University conferred on Dr. A. J. E. Welch, 236
  Retirement of Prof. J. R. Partington from the chair of chemistry at Queen Mary College, 319
  Appointment of Dr. M. J. S. Dewar to the chair of chemistry at Queen Mary College, 319
  Appointment of W. B. Emery to the Edwards chair of Egyptology at University College, 368
  Appointment of Dr. E. Glaister to the University readership in mechanical engineering at the Imperial College of Science and Technology, 368
  Appointment of T. W. Hutchison and R. Turvey to University readerships in economics at the London School of Economics and Political Science, 368
  Title of professor of veterinary anatomy in the University conferred on James McCunn, 368
  Grant of £10,000 from the Nuffield Foundation for research in biophysics at King's College, 454
  Appointment of Dr. C. W. Allen to the Perrin chair of astronomy at University College, 500, 1025
  Appointment of Dr. Ruth Bowden to the University chair of anatomy at the Royal Free Hospital School of Medicine, 683
  Appointment of Dr. R. J. Harrison to be head of the Department of Anatomy at the London Hospital Medical College with the title of University reader in anatomy, 683
  Appointment of A. G. Smith to the University readership in applied thermodynamics at the Imperial College of Science and Technology, 770
  Degree of D.Sc. conferred on J. G. Boswell, Miss M. S. Leslie, Miss L. M. Pickford and F. L. Warren, 770
  Degree of D.Sc.(Eng.) conferred on F. W. Preston, 770
  Degree of D.Sc. conferred on D. R. Bates, Prof. C. H. Gray and Miss Florence N. David, 940
University of Manchester : Appointment of Dr. A. C. B. Lovell to the newly created chair of radio-astronomy, 17
  Retirement of F. Scholefield as head of the Department of Textile Chemistry in the Manchester College of Technology, 17
  The New Universal Digital Computing Machine at the (Dr. T. Kilburn), 95
  Appointment of Dr. Zdenek Kopal to the chair of astronomy, 234
University of Manchester, 1851–1951, *review* by Prof. A. D. Ritchie, 846
University of Nottingham : Research Discussions on Engineering Technology, 455
University of Oxford : Honorary degree of D.Sc. conferred on Dr. G. G. Simpson, 189
  Election of Prof. C. A. Coulson as Rouse Ball professor of mathematics, 236
  Opening of the new building of the Department of Botany by Lord Rothschild, 690
  Grant of £10,000 from the Rockefeller Foundation of New York for the Dyson Perrins Laboratory in aid of research in organic chemistry, 813
University of Queensland : Appointment of John Francis to the chair of preventive medicine within the Veterinary Faculty, 856
University of Reading : Honorary degree of D.Litt. conferred on Sir John Beazley and Sir Frank Stenton, 147
  Honorary degree of D.Sc. conferred on Sir John Russell and Sir Henry Tizard, 147
  Report for 1950 of the National Institute for Research in Dairying, 1074
University of St. Andrews : Fifth Mathematical Colloquium, 321
University of Sheffield : Appointment of Dr. M. A. G. Kaye to be lecturer in biochemistry, 19
  Appointment of Dr. W. S. Bullough to be honorary lecturer in zoology, 19
  Appointment of Dr. R. Wheeler Haines as senior lecturer in anatomy, 103
  Appointment of G. C. Briggs and W. Johnson as lecturers in mechanical engineering, 103
  Appointment of Dr. R. P. N. Jones and M. L. Meyer as lecturers in the Postgraduate School of Applied Mechanics, 103
  Appointment of B. A. Bilby as Sorby Research Fellow in the Metallurgy Department, 189
  Appointment of Dr. T. H. Barton as lecturer in electrical engineering, 726
  Appointment of Dr. W. H. Evans, Dr. H. C. Grimshaw, Dr. E. M. Guenault, Dr. W. C. F. Shepherd and Dr. F. V. Tideswell as honorary lecturers in mining, 726
  Award of the John Stokes Research Fellowship to H. L. Kornberg, 726
  Award of a Knoop Research Fellowship in Economics to D. C. Corner, 726
University of Sheffield (Committee of the Royal Society and the) : Appointment of B. A. Bilby as Sorby Research Fellow in the Metallurgy Department of the University of Sheffield, 189
University of Sydney : Chemistry at the—Gift for New Building, 110
University of Wales : Honorary degree of D.Sc. conferred on Sir David Brunt, 147
University College, Ibadan : Appointment of Prof. J. P. Andrews as vice-president and professor of physics, 17
  Appointment of R. Pattison as head of the Engineering Department, 17

University College, London : Appointment of Dr. Bernhard Katz to the University of London chair of biophysics, 18
  Title of professor emeritus of physiology in the University of London conferred on Prof. A. V. Hill, 147
  Title of professor emeritus of zoology and comparative anatomy in the University of London conferred on Prof. D. M. S. Watson, 147
  Title of professor emeritus of chemical engineering in the University of London conferred on Prof. H. E. Watson, 147
  Appointment of W. B. Emery to the Edwards chair of Egyptology, 368
  Appointment of Dr. C. W. Allen to the Perren chair of astronomy, 500, 1025
University College of North Staffordshire Appointment of Dr. A. M Macbeath as lecturer in mathematics, 19
  Appointment of E. M. Yates and Dr. Monica M. Cole as assistant lecturers in geography, 19
  Appointment of Dr. D. E. Davies and A. A. Shepherd as assistant lecturers in physics, 19
  Appointment of T. H. White and H. Spedding as assistant lecturers in chemistry, 19
  Appointment of Ruth M. Badcock as assistant lecturer in biology, 19
  Appointment of F. Moseley and R. Barrass as assistant lecturers in geology, 19
  Conference on Cationic Polymerization, 545
University College, Southampton : Appointment of Dr. D. J. E. Ingram as research fellow in the Department of Electronics, 984
  New Department of Zoology opened by Prof. J. Z. Young, 1107

TITLE INDEX

ABORIGINES (Australian) : Antiquity of the (Edmund D. Gill), 982
Abortion in Cattle : Erythrocyte Antibodies as a Cause of (J. Laing and F. Blakemore), 656
Abortion Virus (Sheep) : Use of a, as a Test Virus for Chemotherapy Work (Dr. Lois Dickinson and G. W. Inkley), 37
Abrasion and Wear (Rubber-Stichting Symposium on), 276
Absence under Full Employment (Hilde Behrend), 993
Absorption : Ferromagnetic Resonance, and a New Transition in $NiOFe_2O_3$ at Low Temperature (Prof. Toshiko Okamura), 162
Absorption of Anti-Nematode Antibodies from Ewe's Colostrum by the New-born Lamb (Daisy B. Filmer and T. J. McClure), 170
Absorption of Sound in Aqueous Solutions of Electrolytes (K. Tamm and G. Kurtze), 346
Absorption Spectra : Ultra-Violet, of Gallium and Indium Monofluorides (D. Welti and R. F. Barrow), 161
Academic Freedom and Civil Rights, 1051
Acceleration : Artificial, of Atomic Particles (Prof. O. R. Frisch), 849
Accelerator for Protons : The Helix as a Linear (D. R. Chick and D. P. R. Petrie), 782
Accident Proneness (Dr. R. MacKeith), 1032
Acetabularia mediterranea studied with Carbon-14 Dioxide : Protein Synthesis in Nucleated and Non-nucleated Halves of (Prof. J. Brachet and Dr. H. Chantrenne), 950
Acetylene Industry and Acetylene Chemistry in Germany during the Period 1939–1945 (Dr. R. Owens and Dr. A. W. Johnson), 939
Acid Frost in Granitization (E. Venkayya), 79
Acid Phosphatase Activity of the Liver of the Rat : Effects of a Protein-free Diet on the Alkaline and (J. O. Ely and M. H. Ross), 323
Acid Phosphatase -Positive and -Negative Cell Islets in the Adrenal Medulla of the Rat : Histochemical Evidence of the Presence of (Dr. O. Eränkö), 250
Acid Tolerance in Plants (Prof. W. Neilson Jones and Ida Levisohn), 791
Acids (Aromatic): Application of Buffered Solvent Systems to the Detection of, by Paper Partition Chromatography (Mona E. Fewster and Dr. David A. Hall), 78
Acids (Organic) : Enhancement of the Normal Reversion-rate of a Serine-less *Escherichia coli* Mutant by certain (Dr. Barbara E. Wright, 1087
  Partition Paper Chromatography of some (Prof. J. Opienska-Blauth, O. Saklawska-Szymonowa and M. Kanski), 511
Acids and Ammonia in Silage : Estimation of Volatile Fatty, by means of Paper Chromatography (Prof. Artturi I. Virtanen and Jorma K. Miettinen), 294
Acoustics of the Royal Festival Hall, London (P. H. Parkin), 264
Acridine Compounds : Pure and Applied Chemistry of, *review* by Dr. J. Walker, 713
Acridines : The (Prof. Adrien Albert), *review* by Dr. J. Walker, 713
Acrylonitrile : Ferric-Ion Catalysed Decomposition of Hydrogen Peroxide and the Polymerization of (Dr. Adolf G. Parts), 79
ACTH : Inactivation of Adrenotropic Hormone, by Plasma (Dr. Max Reiss, F. E. Badrick, I. D. K. Halkerston and C. Plaice), 206
ACTH, Aminopterin and Eosinophil Count : Adrenotropic Hormone (Dr. Vincenzo Traina), 250
Actinomycin from *Streptomyces S-67* : Radiocrystallographic Study and Molecular Weight of (H. Sarlet, J. Toussaint and H. Brasseur), 469
Activation and the Correlation between Male and Female Elements in Fertilization (C. R. Austin), 558
Activity of Hyaluronidase : Effect of Histamine on the (Dr. F. Seelich and P. Hübl), 1125
Activity in a Source of Ionizing Radiation : A Method of making Visible the Distribution of (Prof. W. V. Mayneord, R. C. Turner, S. P Newbery and H. J. Hodt), 762
Acustica, a new International Journal, 682
N-Acylaspartic Acids : Racemization of (Dr. C. C. Barker), 908
Adams Prize for 1949–50 of the University of Cambridge awarded jointly to Dr. G. K. Batchelor, W. R. Dean and Dr. L. Howarth, 19
Adaptation : The Logic of, *review* by Prof. C. H. Waddington, 1013
Adaptation in Rodent Moles and Insectivorous Moles, and the Theory of Convergence (Dr. G. Eloff), 1001
Adenosine Triphosphate in Muscular Contraction : Dephosphorylation of (W. F. H. M. Mommaerts and Joseph C. Rupp), 957
Adrenal Ascorbic Acid : Influence of Adrenotropic Hormone Fractions on 'Adrenal Repair' and on (H. B. F. Dixon, M. P. Stack-Dunne, Prof. F. G. Young and D. B. Cater), 1084
Adrenal Medulla of the Rat : Histochemical Evidence of the Presence of Acid Phosphatase -Positive and -Negative Cell Islets in the (Dr. O. Eränkö), 250
'Adrenal Repair' : Influence of Adrenotropic Hormone Fractions on, and on Adrenal Ascorbic Acid (H. B. F. Dixon, M. P. Stack-Dunne, Prof. F. G. Young and D. B. Cater), 1084
Adrenalectomized Rats : Effect of Ascorbic Acid on Skin Permeability in (Bengt H. Persson), 119
Adrenaline : Active Relaxation of Unstriated Muscle produced by (Sunita Inderjit Singh and Prof. Inderjit Singh), 829
Adrenaline and *nor*-Adrenaline on Paper Chromatograms : A Colour Reaction distinguishing between (Dr. A. J. Glazko and W. A. Dill), 32
Adrenals (Hog) : Isolation of 17-Hydroxycorticosterone and 17-Hydroxy-11-dehydrocorticosterone from (P. B. Baker, F. Dobson and S. W. Stroud), 114
Adrenocorticotrophin : Potentiation by, of the Diabetogenic Action of Growth-Hormone Preparations (Dr. E. Reid), 878
Adrenotropic Hormone : An Extra-Adrenal Action of (Prof. Hans Selye), 149
Adrenotropic Hormone (ACTH) : Inactivation of, by Plasma (Dr. Max Reiss, F. E. Badrick, I. D. K. Halkerston and C. Plaice), 206
Adrenotropic Hormone (ACTH), Aminopterin and Eosinophil Count (Dr. Vincenzo Traina), 250
Adrenotropic Hormone on Ion-exchange Columns : Chromatography of H. B. F. Dixon, Dr. Stanford Moore, M. P. Stack-Dunne and Prof. F. G. Young), 1044
Adrenotropic Hormone Fractions : Influence of, on 'Adrenal Repair' and on Adrenal Ascorbic Acid (H. B. F. Dixon, M. P. Stack-Dunne, Prof. F. G. Young and D. B Cater), 1084
Adsorption on Coal (Dr. G. Garrod Thomas), 474
Adsorption of Hydrogen on Nickel Catalysts : Activated (Dr. G. C. A. Schuit and N. H. de Boer), 1040
Adsorption of Water and Methanol on Coal (J. A. Lecky, W. Keith Hall and Robert B. Anderson), 124
Adsorption Chromatography : A Simplified Coupled Filter System for (Dr. David A. Hall), 124
Adsorption Isotherm : Hüttig's (Otto Theimer), 873
Aerobacter sp. : Direct Oxidation of Glucose by (Dr. J. De Ley and S. Cornut), 515
Aerobiology : Arctic (Prof. Nicholas Polunin), 718
Æther ? : Is there an (Prof. P. A. M. Dirac), 906
Aether and Electricity : A History of the Theories of (Sir Edmund Whittaker), revised edition, *review* by Prof. W. H. McCrea, 1053
Afferent Limb of the Myotatic Reflex Arc (Dr. A. K. McIntyre), 168
Africa (East) : Industrial Research in, 319
  Medical Research in, 898
Africa (South) : Breeding of Pilchards off the West Coast of (Dr. C. Von Bonde and D. H. Davies), 952
  Forestry and Conservation in, 726
  Prehistoric Cave Paintings in (J. R. Harding), 275
  Ticks of (Gertrud Theiler), 589
Africa (South-West) : Breeding Ground of Pilchards off the Coast of (Dr. T. J. Hart and N. B. Marshall), 272
Africa (West) : Unusual Features of the Root System of the Oil Palm of (J. O. Wright), 748
African Horse-sickness Virus Vaccine : An Improved Diluent for the Production of (A. Polson, J. Dent, S. M. Lawrence and P. J. van Rooy), 655
African Soils (Central) : Temperature Characteristics of the Microflora of (H. Laudelout and J. Meyer), 791
Agar : Permanent Preparations of Fungi growing on (Dr. C. L. Duddington and Sylvia M. Dixon), 38
Agar-Plate Method : Detection of Enzymes by the, and its Application to Paper Chromatography (W. W. Reid), 739
Age ? : Cube-Edges of Uraninites as a Criterion of (B. Wasserstein), 380
Age of Parents important in Sheep ? : Is (R. A. Barton), 37
Age in the Resistance of Bacterial Cells : Variation with (Dr. Helen R. White), 828
Agitating in Liquid Media : Mixing and (Institution of Chemical Engineers Conference on), 376
Agricultural Machinery at the Science Museum, 145
Agricultural Research in the Groundnut Scheme, 1947–51 (Dr. A. H. Bunting), 804
Agricultural Scholarships : Postgraduate (Ministry of Agriculture and Fisheries Awards), 683
  Postgraduate (Department of Agriculture for Scotland Awards), 589
Agriculture : Experimental (Dr. E. M. Crowther), 232
Air (Stratosphere) : Variations in the Chemical Composition of (Dr. K. F. Chackett, Prof. F. A. Paneth, P. Reasbeck and B. S. Wiborg), 358
Air Almanac and the *American Air Almanac* : Unification of the, 413
Albino : Colour Vision of an (Dr. R. W. Pickford), 954
Alchemy and Alchemists (Prof. John Read), 759
Alcohols : Paper Partition Chromatography of, using the Potassium Xanthogenates (Tatsuo Kariyone, Dr. Yohei Hashimoto and Mutsuo Kimura), 511
Alga from Stonehenge : A Rare (M. A. Pocock), 524
Algae : Unicellular, as a Source of Food (Dr. M. J. Geoghegan), 426
Algae (Nitrogen-fixing Blue-Green) : Effect of, on the Growth of Rice Plants (Dr. A. Watanabe, S. Nishigaki and C. Konishi), 748
Ali-esterase of Rabbit Polymorphonuclear Leucocytes (Esther Wong), 80
Alimentazione e Dietologia : *Bollettino dell'Istituto di*, Vol. 1, Nos. 1 and 2, 18
Aliphatic and Aromatic Amines : Dipole Moments of (Dr. E. G. Cowley), 705
Alkali Halide Crystals : Elastic Constants of (Sir K. S. Krishnan and Dr. S. K. Roy), 869, 983
Alkaline Decomposition of Amino-acids (Dr. J. M. Bremner), 518
Alkaline Phosphatase and Contractile Proteins (Prof. J. F, Danielli), 464
Alkaline and Acid Phosphatase Activity of the Liver of the Rat : Effects of a Protein-free Diet on the (J. O. Ely and M. H. Ross), 323
Alkaloid of *Dioscorea hispida*, Dennst. (A. R. Pinder), 1090
Alkaloids : Separation of, by Paper Chromatography (J. E. Carless and H. B. Woodhead), 203
  The Technology and Chemistry of (Frank E. Hamerslag), *review*, 311
Allergy : Antihistaminic Agents in (New York Academy of Sciences Conference on), 499
Alloys : Metals and (British Association, Sections B (Chemistry) and G (Engineering), Discussion on), 414

TITLE INDEX

α-Particle Irradiation : Chemical Effects in Liquids due to (Prof. P. I. Dee and E. W. T. Richards), 736
Alston (R. P.) Memorial Prize of the Royal Aeronautical Society awarded to R. J. Falk, 498
Altitude : Effect of, on the Estimation of 'Crude Fibre' (J. R. Todd), 76
  Relationship of Aphid Density to (C. G. Johnson and H. L. Penman), 337
Alumina Production : Technology of, *review*, 397
Aluminium : Tonerde und—Ergebnisse und Erfahrungen aus der Betriebspraxis 1920–1950 (Dr. Wilhelm Fulda und Dr. Hans Ginsberg), Teil I, *review*, 397
Aluminium-28 : 31-keV. Excited State of (R. D. Smith and R. A. Anderson), 429
Aluminium Oxide Films . Structure of Amorphous (Dr. H. G. F. Wilsdorf), 600
Aluminium Sulphate/Sulphuric Acid/Water Solid Phase Determinations in the System, using Tracer Technique (Duncan Taylor and Richard Scott), 520
Alvarenga Prize for 1951 of the College of Physicians of Philadelphia awarded to Dr. George W. Thorn, 103
America (Eastern North) : Deciduous Forests of (Prof. E. Lucy Braun), *review* by Sir Edward Salisbury, 309
American Air Almanac : Unification of the *Air Almanac* and the, 413
American Chemical Society and International Chemistry (Sir Eric K. Rideal), 765
American Deciduous Forests, *review* by Sir Edward Salisbury, 309
American Education . Importance of Science in (Ernst A. Hauser), 866
American Forage and Pasture Crops, *review* by J. O. Green, 575
American Hydnums, *review* by E. J. H. Corner, 1015
American Resources, *review* by Prof. L. Dudley Stamp, 485
American Scientific Mission to West Germany, 320
American (South) Indians . Handbook of (edited by Julian H. Steward), Vol. 6, *review* by Dr. G. H. S. Bushnell, 575
Americans : The First, *review* by Dr. G. H. S. Bushnell, 92
Amines (Aliphatic and Aromatic) : Dipole Moments of (Dr. E. G. Cowley), 705
Amino Group of Lysine . Reaction between Glucose and the Terminal (R. S. Hannan and C. H. Lea), 744
Amino Groups of Collagen : Free (J. H. Bowes and J. A. Moss), 514
α- and ε-Amino Groups : Relative Importance of Free, for the Biological Activity of the Growth Hormone (Dr. E. Reid), 955
Amino-Acid Chromatograms : Conservation of (Dr. E. Kawerau and Prof. T. Wieland), 77
Amino-Acid Composition of Crotoxin (Dr. K. H. Slotta and J. Primosigh), 696
Amino-Acids : Alkaline Decomposition of (Dr. J. M. Bremner), 518
  A New Paper Chromatography Solvent for (F. Bryant and B. T. Overell), 167
Amino-Acids containing Cysteine Artefacts in the Chromatography of Mixtures of (M. B. Van Halteren), 1090
Amino-Acids of Molasses and other Beet-sugar Industry By-products : Chromatographic Analysis of (Eugenio Mariani and Giorgio Torraca), 959
Amino-Acids during Paper Chromatography with Solvents completely Miscible with Water : Effect of Temperature on the R_F Values of the (D. P. Burma), 565
Amino-Acids of Silk Sericin (J. T. B. Shaw and Dr. S. G. Smith), 745
Amino-Acids, Peptides, Proteins and other Buffering Substances on Paper A New Method for the Detection of (Dr. J. Porath and P. Flodin), 202
4-Amino-imidazole-5-carboxamide : Ribosidation of, by *Escherichia coli* (R. Ben-Ishai, Dr. Ernst D. Bergmann and B. E. Volcani), 1124
Aminopterin . Growth Inhibition in Amphibian Larvæ by 4-Amino Pteroyl Glutamic Acid (R. M. Rosenbaum and J. T. Velardo), 424
Aminopterin and Eosinophil Count : Adrenotropic Hormone (ACTH), (Dr. Vincenzo Traina), 250
4-Amino Pteroyl Glutamic Acid (Aminopterin) : Growth Inhibition in Amphibian Larvæ by (R. M. Rosenbaum and J. T. Velardo), 424
Ammonia (Liquid) Tetrabromothiophene from 2-Bromothiophene by means of Sodium Acetylide in (A. Vaitiekunas and Prof. F. F. Nord), 875
Ammonia in Silage Estimation of Volatile Fatty Acids and, by means of Paper Chromatography (Prof. Artturi I. Virtanen and Jorma K. Miettinen), 294
Ammonium and Thiocyanate Ions in Soil : Microbiological Oxidation of (Dr. H. Gleen), 117
Amoeba proteus : Oxygen Uptake of Nucleated and Non-nucleated Halves of (Prof. J. Brachet), 205
Amphibian Larvæ . Growth Inhibition in, by 4-Amino Pteroyl Glutamic Acid (Aminopterin), (R. M. Rosenbaum and J. T. Velardo), 424
Amphipoda (British Freshwater) Distribution of (G. Fryer), 435
α-Amylase of *Aspergillus oryzae* : Crystallization of the (Dr. Ed. H. Fischer and R. de Montmollin), 606
Anæsthetics The Mode of Action of (T. A. B. Harris), *review* by Dr. H. Roy Blades, 1098
Analyses of the Deep-Sea Cores collected by the Swedish Deep-Sea Expedition 1947–48 International Co-operation in the (C. D. Over), 148
Analysing several Sera Simultaneously : An Electrophoresis Apparatus for (Dr. A. Polson), 996
Analysis : Radiochemical Techniques in (Physical Methods Group of the Society of Public Analysts and other Analytical Chemists Discussion on), 153
Analysis of Soaps : Methods for the (British Standard 1715 1951), 683
Anaphylatoxin : Histamine Release by (Prof. N. Rocha e Silva, O. Bier and M. Aronson), 465
Anatomy of the Gorilla (The Studies of Henry Cushier Raven), arranged and edited by William King Gregory, *review*, 926
Animal (New-born) : Histological Changes in the Epithelium of the Small Intestine during Protein Absorption in the (Dr. R. S. Comline, H. E. Roberts and D. A. Titchen), 84
Animal Evolution (G. S. Carter), *review* by Prof. Sewall Wright, 351
Animal Nutrition : Tropical, *review* by Dr. John Hammond, 440
Animal Nutrition in relation to Soil and Climatic Factors : Plant and (British Commonwealth Scientific Official Conference : Specialist Conference in Agriculture, Australia 1949, Proceedings), 499
Animal Psychology, *review* by Alec Rodger, 134
Animals : Effect of Diseases on the Serum Albumin of (A. Polson), 421
  Limits to Intensive Production in (British Association, Section M (Agriculture), Symposium on), 490
  Senses and Behaviour of (British Association, Sections D (Zoology) and J (Psychology), Discussion on), 643
  Trace Elements in Plants and (Prof. Walter Stiles), second edition, *review* by K. W., 486
Animals (Bottom) : Density of, on the Ocean Floor (Prof. R. Spärck), 112
Animals (Wild) : Man's Control of (David Seth-Smith), 26
Animals of Scotland (Glasgow Art Gallery and Museum Booklet on), 413
Animals treated with Growth Hormone The Hyperglycæmic Action of Blood from (Dr. J. Bornstein, Dr. E. Reid and Prof. F. G. Young), 903
Animals and Forestry (British Association, Sections D (Zoology) and K* (Forestry), Symposium on), 449
Animals and Plants : Marine, *review* by Dr. N. B. Eales, 1014
Animaux Quaternaires découvertes en Belgique : Les représentations de l'Homme et des (Prof. Francois Twiesselmann), 1026
Anionotropic Change (Bimolecular) : Demonstration of (Dr. B. D. England and Prof. E. D. Hughes), 1002
Anisotrophy of γ-Radiation from Oriented Cobalt-60 Nuclei : An Experiment on Nuclear Alignment—the (J. M. Daniels, Dr. M. A. Grace and F. N. H. Robinson), 780
Anobium punctatum De Geer . Digestion of Alpha-Cellulose by Larvæ of (D. Spiller), 209
Anopheles spp. : Complete Sporogonic Development of *Plasmodium berghei* in Experimentally Infected (Dr. M. Yoeli and Miss W. J. Wall), 1078
Ant Species An Insect Pest of Coconuts and its relationship to certain (M. J. Way), 302
Antarctic New Map of the (H. P. Kosack), 275
Antarctica : A Camera in (Alfred Saunders), *review* by Seton Gordon, 52
Antarktis : Zur Frage der Namengebung in der (Dr. J. Georgi), 275
Antennæ and Mating Behaviour in *Drosophila melanogaster* (Dr. Michael Begg and Elsie M. Packman), 953
Anthropology Genetics and, *review* by Dr. J. S. Weiner, 1054
  Statistical Methods in (Dr. J. Bronowski and W. M. Long), 794 ; (Dr. F. Yates and M. J. R. Healy), 1116 ; (E. H. Ashton and Prof. S. Zuckerman), 1117
  Cultural, of the Rodiyas (M. D. Raghavan), 813
Anthropology (Social) : The Foundations of (Prof. S. F. Nadel), *review* by Mrs. Mary Douglas, 799
Anthropology and Social Studies, *review* by Mrs. Mary Douglas, 799
Antibiotic from Lactobacilli : 'Lactobacillin', an (Dorothy M. Wheater, Dr. A. Hirsch and Dr. A. T. R. Mattick), 659
Antibiotics : Mode of Action of, in Stimulating Growth of Chicks (M. E. Coates, C. D. Dickinson, G. F. Harrison, Dr. S. K. Kon, Sheila H. Cummins and W. F. J. Cuthbertson), 332
Antibodies (Anti-Nematode) : Absorption of, from Ewe's Colostrum by the New-born Lamb (Daisy B. Filmer and T. J. McClure), 170
Antibodies (Bacterial): Transfer of, from the Hen to the Chick (A. Buxton), 657
Antibodies (Local) : Improved Sampling Method for Demonstration of, in the Vagina (Dr. L. Szabó), 171
Antiferromagnetics at the Néel Point : Anomalous Variation of Young's Modulus of (Dr. R. Street and B. Lewis), 1036
Antifungal Substances in *Brassica rapa*, *Brassica oleracea* and *Beta vulgaris* : Occurrence of (Dr. F. C. Gerretsen and Netty Haagsma), 659
Antigen : Complement Fixing, in *T5 coli* Bacteriophage (Phyllis M. Rountree), 34
Antigen (Specific Purified) : Preparation of the, of Canine Hepatitis Virus and Antiserum for Serological Studies (Dr. N. M. Larin), 745
Antigens in the Developing Newt Embryo (R. M. Clayton), 120
Antihistamine Effect of, on the Reticulo-endothelial System—Investigation of Reticulo-endothelial Function with the aid of Radioactive Chromium Phosphate (Dr. Elemér R. Gabrieli), 467
Antihistamines . Geometrical Isomers in a Series of (D. W. Adamson, P. A. Barrett, J. W. Billinghurst, A. F. Green and T. S. G. Jones), 204
Antihistaminic Agents in Allergy (New York Academy of Sciences Conference on), 499
Antilymphocytic Serum Effect of, on Suspensions of Lymphocytes *in vitro* (Dr. Michael Woodruff and Bruce Forman), 35
Antimalarial Activity : A Metabolite of 'Paludrine' with High (Dr. H. C. Carrington, Dr. A. F. Crowther, Dr. D. G. Davey, Dr. A. A. Levi and Dr. F. L. Rose), 1080
Anti-Nematode Antibodies : Absorption of, from Ewe's Colostrum by the New-born Lamb (Daisy B. Filmer and T. J. McClure), 170
Antiquities : Major Visible, in Great Britain before 1066 (Ordnance Survey), 101
Antiquity of the Australian Aborigines (Edmund D. Gill), 982
Antirickettsial Properties : New Derivatives of Nitroparaffins and their Antitubercular and (Prof. T. Urbanski), 562 ; *erratum*, 984
Antiseptics : Mechanism and Evaluation of (New York Academy of Sciences Conference on), 367
Antitubercular Activity of some 8-Hydroxyquinoline Derivatives (Prof. T. Urbanski, Prof. S. Slopek and Dr. J. Venulet), 29
Antitubercular and Antirickettsial Properties : New Derivatives of Nitroparaffins and their (Prof. T. Urbanski), 562 ; *erratum*, 984
Antituberculous Effect of certain Surface-Active Polyoxyethylene Ethers in Mice (Dr. J. W. Cornforth, Dr. P. D'Arcy Hart, R. J. W. Rees and J. A. Stock), 150
Antivitamin D Factor (A. B. Grant), 789
Aphid Density : Relationship of, to Altitude (C. G. Johnson and H. L. Penman), 337
Aphids : Benefits to, from Feeding on Galled and Virus-infected Leaves (Dr. J. S. Kennedy), 825
Apple Fruit : Organic Acids of the (A. C. Hulme and Dr. T. Swain), 254
Applied Physics, British Journal of (edited by Dr. H. R. Lang), Vol. 1, 1950, *review* by S. Weintroub, 7
Apyrases of Moulds (P. S. Krishnan), 171
Aqueous Solutions of Electrolytes : Absorption of Sound in (K. Tamm and G. Kurtze), 346
Archæological Dating : Errors in the Carbon-14 Method of, 725
Archæological Dating of the Climatic Change in North Europe about A.D. 1300 (Dr. Axel Steensberg), 672

TITLE INDEX

Archæological Materials : Radio-carbon Datability of Peat Marl, Caliche and (H. H. Bartlett), 725
Arctic Aerobiology (Prof. Nicholas Polunin), 718
Arms-Race : Could an, End without Fighting? (Dr. L. F. Richardson), 567, 920 ; (M. R. Horne), 920
Aromatic Acids : Application of Buffered Solvent Systems to the Detection of, by Paper Partition Chromatography (Mona E. Fewster and Dr. David A. Hall), 78
Aromatic Amines : Dipole Moments of Aliphatic and (Dr. E. G. Cowley), 705
Aromatic Compounds : Chemistry of the Oxidative Metabolism of certain, by Micro-organisms (Dr. W. Charles Evans, B. S. W. Smith, Prof. R. P. Linstead and Dr. J. A. Elvidge), 772
Arsenic : Mechanical Properties of α-Solid Solutions of Copper, with Zinc, Gallium, Germanium and (Dr. N. P. Allen, T. H. Schofield and A. E. L. Tate), 378
Art of Government : The Science and (Lord Hankey), 571
Artefacts in the Chromatography of Mixtures of Amino-acids containing Cysteine (M. B. Van Halteren), 1090
Arthropods (Mandibulate) : Comparative Studies on the Jaws of (R. E. Snodgrass), 682
Artificial Acceleration of Atomic Particles (Prof. O. R. Frisch), 849
Artificial Insemination of Birds (G. C. van Drimmelen), 726
Artificial Light : Inhibitory Action of, on the Sexual Season of the Ewe (E. S. E. Hafez), 336
Artificial Production of Atmospheric Precipitation : Natural and (British Association, Section A (Mathematics and Physics), Discussion on), 533
Arylhydroxylamine Rearrangement : A New View of the (H. E. Heller, Prof. E. D. Hughes and Prof. C. K. Ingold), 909
Ascorbic Acid : Effect of, on Skin Permeability in Adrenalectomized Rats (Bengt H. Persson), 119
Ascorbic Acid (Adrenal) : Influence of Adrenotropic Hormone Fractions on 'Adrenal Repair' and on (H. B. F. Dixon, M. P. Stack-Dunne, Prof. F. G. Young and D. B. Cater), 1084
Asellus meridianus Racovitza, with Low Chromosome Number : An Isopod, (S. Muldal), 1127
Asia (South-east) : History of Science and Technology in India and (Dr. Joseph Needham), 64, 1048 ; (Dr. S. L. Hora), 1047
Aspergillus niger : Zinc Requirements of (Dr. G. N. Robinson), 210
Aspergillus niger on various Substrates : Chromatographic Detection of Pyruvic, Dimethylpyruvic and α-Ketoglutaric Acids in Cultures of (Dr. T. K. Walker, A. N. Hall and J. W. Hopton), 1042
Aspergillus oryzae : Crystallization of the α-Amylase of (Dr. Ed. H. Fischer and R. de Montmollin), 606
Assessment of Vitamin A Potency by Spectrophotometry : Pure *All-trans* Vitamin A Acetate and the (J. Boldingh ; H. R. Cama, Dr. F. D. Collins and Prof. R. A. Morton ; N. T. Gridgeman ; O. Isler and M. Kofler ; R. J. Taylor ; A. S. Welland and T. Bradbury), 598
Astronautics : Second International Congress on (British Inter-planetary Society), 369 ; (J. Humphries), 733
Astronomer : The Home Life of an, *review* by Prof. F. J. M. Stratton, 440, 1008 ; (Mrs. Margaret Wilson), 1007
Astronomer Royal : Ninth, the Life of Frank Watson Dyson (Margaret Wilson), *review* by Prof. F. J. M Stratton, 440
Astronomical Photographs from the Yerkes Observatory : Catalogue of (edited by Thornton Page), 412
Astronomy : Photography in (Dr. E. W. H. Selwyn), *review* by L. V. Chilton, 485
Astronomy at the Cape of Good Hope : Annual Report for 1950, 1114
Astronomy in the University of Manchester, 234
Astronomy at University College, London, 1025
Atlas : The Oxford (edited by Brigadier Sir Clinton Lewis and Colonel J. D. Campbell), *review*, 1016
Atmospheric Oxygen Bands in Emission from Neon–Oxygen Mixtures, and in Night Sky and Auroral Luminescences (G. Kvifte), 741
Atmospheric Precipitation : Natural and Artificial Production of (British Association, Section A (Mathematics and Physics), Discussion on), 533
Atom : The Primeval (Canon Georges Lemaître), translated by Betty H. and Serge A. Korff, *review* by Prof. T. G. Cowling, 259
Atomic Energy in Great Britain : Development of, 61
Atomic Heating System at Harwell, 898
Atomic Heats of Gases : A New Method for Measuring the (Prof. H. S. Gregory and I. I. Sheriff), 1123
Atomic Particles : Artificial Acceleration of (Prof. O. R. Frisch), 849
Atomic Reminiscences, *review* by Prof. O. R. Frisch, 6
Atoms : New (Otto Hahn), *review* by Prof. O. R. Frisch, 6
Atoms Encaged—a New Type of Compound (H. M. Powell), 11
Auditory 'Click' Stimuli : Tone Sensation produced by Repetitive Trains of (W. T. Catton), 882
Audubon Water Bird Guide (Richard H. Pough), *review* by Frances Pitt, 355
Auroral Luminescences : Atmospheric Oxygen Bands in Emission from Neon–Oxygen Mixtures, and in Night Sky and (G. Kvifte), 741
Auroras : The Theory of Magnetic Storms and (Prof. Sydney Chapman), 86
Auroras and Luminous Night Clouds (J. Paton), 487
Australia : The Geology of the Commonwealth of (the late Sir T. W. Edgeworth David), *review* by Prof. C. E. Tilley, 131
  Land Utilization in (Prof. C. M. Wadham and Prof. G. L. Wood), second edition, *review*, 928
  Rabbit Control in—Problems and Possibilities (J. E. Nichols), 930
Australia (Western) : A Handbook of the Birds of (with the exception of the Kimberley Division), (D. L. Serventy and H. M. Whittell), second edition, *review* by Dr. A. J. Marshall, 441
Australian Aborigines : Antiquity of the (Edmund D. Gill), 982
Australian Fisheries (edited by I. G. Macinnes), *review* by C. F. H., 973
Australian Geology—a Regional Synthesis, *review* by Prof. C. E. Tilley, 131
Australian Merino Lambs : Birth Coats of (P. G. Schinckel), 698
Australian Timbers for Veneers : Suitability of (A. J. Watson and H. G. Higgins), 640
Australian (West) Flora (Sir Edward Salisbury), 57
Azimuts von Fernbeben aus Oberflächenwellen : Über die Bestimmung des (Prof. W. Hiller), 1106
Azulenes : A New Route to (Dr. E. A. Braude and W. F. Forbes), 874

BACILLUS spec. div. : *Caulobacter versus* (A. L. Houwink), 654
Bacillus megatherium : Glucose and Lysogenesis in (H. L. Ehrlich and S. G. Knight), 658
Bacteria (Nitrifying) : Myxobacteria Mistaken for (Joyce B. Grace), 117 ; (Dr. Jane Meiklejohn), 561
Bacteria (Phytopathogenic) : Action of, on Pectate Gel (Dr. K. A. Sabet and Dr. W. J. Dowson), 605
Bacteria (Sulphate-reducing) : Iron/Sulphide Ratios in Corrosion by (C. J. P. Spruit and J. N. Wanklyn), 951
Bacterial Antibodies : Transfer of, from the Hen to the Chick (A. Buxton), 657
Bacterial Canker Organism (Cherry), *Pseudomonas mors-prunorum* Wormald : The Leaf Scar as an Avenue of Infection for the (J. E. Crosse), 560
Bacterial Cells : Variation with Age in the Resistance of (Dr. Helen R. White), 828
Bacterial Cytology : Elements of (Prof. Georges Knaysi), second edition, *review* by Dr. K. A. Bisset, 439
Bacterial Enzyme Preparations oxidizing Inositol and their Inhibition by Colchicine (Robert E. Franzl and Prof. Erwin Chargaff), 955
Bacterial Flagella (Prof. Adrianus Pijper), 749 ; (Dr. Claes Weibull), 750
Bacterial Growth : Changes in Electrical Conductivity during (Prof K. Krishnamurti and S. R. Kate), 170
Bacterial Growth-stimulation : Nature of the Factor in Soil-extract Responsible for (Dr. C. B. Taylor), 115
Bacterial Nucleic Acids : Localization of, and Mechanism of the Gram Reaction (Heiner Hoffman), 464
Bacterial Virus : Mutation in a (Brigadier J. S. K. Boyd), 994
Bacteriology : Applied Mycology and (L. D. Galloway and Dr. R. Burgess), third edition, revised by L. D. Galloway, *review* by Dr. John Grainger, 7
  Practical Dairy (Prof. Paul R. Elliker), *review*, 621
Bacteriology of Silage : Chemistry and (Society for Applied Bacteriology Symposium on), 730
Bacteriophage (T5 *coli*) : Complement Fixing Antigen in (Phyllis M. Rountree), 34
Baly Medal of the Royal College of Physicians awarded to Prof. G. de Hevesy, 189
Barium Stearate Substrate deposited on Mica : Epitaxis of Rubidium Iodide on a (A. A. Fuller), 471, 899
Base Saturation and Crop Response to Phosphate in Acid Soils : Relationship between (Dr. H. F. Birch), 388
Bath (Cold) : Use of Solid Carbon Dioxide in preparing a (L. G. E. Bell), 456
Bauschinger Effect in Metals : Magnetic Properties, Internal Strains, and the (N. H. Polakowski), 838
Beckly Social Service Lecture (Sir George Schuster), 842
Beech in Great Britain : General Volume Table for (F. C. Hummel and W. T. Waters), 111
Beet Yellows Virus (H. L. Nixon and M. A. Watson), 523
Beet-sugar Industry By-products : Chromatographic Analysis of Amino-acids of Molasses and other (Eugenio Mariani and Giorgio Torraca), 959
Behaviour of Animals : Senses and (British Association, Sections D (Zoology) and J (Psychology), Discussion on), 643
Belgique : Les représentations de l'Homme et des Animaux Quaternaires découvertes en (Prof. Francois Twiesselmann), 1026
Belgium : Quaternary Finds in, 1026
  Scientific Research in Industry in, 420
Bennett (R. B.) Empire Prize for 1951 awarded by the Royal Society of Arts to E. Bruce Levy, 456
Benzaldehyde : Mechanisms of Oxidation of (M. F. R. Mulcahy and I. C. Watt), 123
Benzene (Carbon-labelled) : A Convenient Synthesis of (H. S. Turner), 73
Berkeley's Scientific Works, *review* by Prof. A. D. Ritchie, 1014
Berlin : Science in (Dr. F. P. Bowden), 237
Beryllium (Metallic) : A New Calculation of the Cohesive Energy of (B. Donovan), 836
Beta vulgaris : Occurrence of Antifungal Substances in *Brassica rapa*, *Brassica oleracea* and (Dr F. C. Gerretsen and Netty Haagsma), 659
Bibliography of Electron Microscopy (edited by Dr. V. E. Cosslett), *review* by L. V. Chilton, 928
Bibliography of French Mathematics and Astronomy during 1940–48, 188
Bibliography of Seismology, 1106
Bile Secretion in Chick Embryos : Stimulation of, by Cortisone (M. M. Mosbaugh and Prof. A. W. Ham), 789
Bimolecular Anionotropic Change : Demonstration of (Dr. B. D. England and Prof E. D. Hughes), 1002
Binary Fatty-acid Systems : Solidification Curves and Crystal Spacings of (M. Fieldes and L. Hartman), 74
Binnengewässer : Die (Dr. G. Huber-Pestalozzi), Band 16, Das Phytoplankton des Süsswassers, Systematik und Biologie, Teil 3, *review* by Prof. F. E. Fritsch, 396
Biochemical Activities of Micro-organisms : A Micro-method for the Examination of the (J. Dingle and G. L. Solomons), 425
Biochemical Effects of Lysergic Acid Diethylamide : Psychological and (Dr. W. Mayer-Gross, Dr. W. McAdam and Dr. J. W. Walker), 827
Biochemistry : Second International Congress of, 456
  Plant (James Bonner), *review*, 4
Biochemistry of the Nucleic Acids (Prof. J. N. Davidson), *review*, 52
Biochemistry in the Taxonomy of Lichens (I. Mackenzie Lamb), 38
Biogeochemistry : Survey of Existing Knowledge of, 3, The Biogeochemistry of Vertebrate Excretion (George Evelyn Hutchinson), *review* by Sir James Scott Watson, 925
Biological Activity of the Growth Hormone : Relative Importance of Free α- and ε-Amino Groups for the (Dr. E. Reid), 955
Biological Approach to Plant Viruses (Dr. J. S. Kennedy), 890
Biological Materials : Preservation of, by Freeze-Drying (Dr. R. J. C. Harris), 851
Biological Method for Evaluating the Efficiency of Insecticides for the Protection of Sheep against Blowfly Strike : A New (O. G. H. Fiedler and R. du Toit), 608
Biological Research in the Soviet Union : Some Aspects of (Science Section of the Society for Cultural Relations between the Peoples of the British Commonwealth and the U.S.S.R. Meeting on), 814

Biological Specimens : X-Ray Microradiography of (Dr. W. Ehrenberg and W. E. Spear), 513
Biology : Analytical (G. Sommerhoff), *review* by Prof. C. H. Waddington, 1013
  New, No. 11 (edited by M. L. Johnson and Michael Abercrombie), 1032
  Unitary, *review* by Prof. C. H. Waddington, 970
Biology in Education, 257
Biology of *Drosophila* (edited by M. Demerec), *review* by H. Oldroyd, 803
Biology and Productivity of Hot and Cold Deserts (Institute of Biology Conference on), 1068
Biophysical Studies of Rheumatoid Connective Tissue (Dr. J. H. Kellgren and Dr. J. Ball, and Prof. W. T. Astbury, Dr. R. Reed and E. Beighton), 493
Biophysics and Biophysical Chemistry : Progress in (edited by Dr. J. A. V. Butler and Prof. J. T. Randall), *review* by Dr. D. P. Riley, 532
Biosynthesis of Tobacco Mosaic Virus by Thiouracil : Inhibition of the (Dr. Barry Commoner and Frank Mercer), 113
Bird Guide : Audubon Water (Richard H. Pough), *review* by Frances Pitt, 355
Bird Migration : Studies in ; being the Collected Papers of H. Chr. C. Mortensen, 1856–1921 (edited by Poul Jespersen and A. Vedel Tåning), *review* by Dr. A. Landsborough Thomson, 216
Birds : Ability of, to Count (Prof. O. Koehler), 373
  Artificial Insemination of (G. C. van Drimmelen), 726
  British (F. W. Frohawk), *review* by Frances Pitt, 263
  Learning Abilities of (W. H. Thorpe), 552
  Territorial Behaviour in (R. W. Nero and J. T. Emlen, Jun.), 1068
Birds (Bower) : Birds of Paradise and (Tom Iredale), *review* by Dr. A. J. Marshall, 135
Birds of a Low Rainfall Region, *review* by Dr. A. J. Marshall, 441
Birds of Paradise and Bower Birds (Tom Iredale), *review* by Dr. A. J. Marshall, 135
Birds of Western Australia (with the exception of the Kimberley Division) : A Handbook of the (D. L. Serventy and H. M. Whittell), second edition, *review* by Dr. A. J. Marshall, 441
Birds and Mammals : Natural History—(David Seth-Smith), *review* by M. A. C. Hinton, 136
Birds' Eggs : Palatability of (Dr. Hugh Cott), 1110
Birth in Man : *ABO* Blood Groups and Sex-Ratio at (Dr. L. D. Sanghvi), 1077
Birth Coats of Australian Merino Lambs (P. G. Schinckel), 698
Blight Resistance in Potato (Dr. William Black), 18
Block for Spore-formation in Yeast : The Cement Block, an Improved (V. Hartelius and E. Ditlevsen), 385
  An Improved (Dr. E. Elion), 1130
Block Design : Application of an Incomplete, to the Assessment of Quality in Cacao (J. A. R. MacLean and Robert Wickens), 434
Blood : Spectrophotometric Determination of Hæmoglobin in (A. A. Khalifa and Prof. M. K. Salah), 915
  The *in vitro* Formation and Disposal of Carbon Monoxide in (Torgny Sjöstrand), 729
Blood (Human) : Dielectric Behaviour of, at Microwave Frequencies (Dr. H. F. Cook), 247
Blood from Animals treated with Growth Hormone : The Hyperglycæmic Action of (Dr. J. Bernstein, Dr. E. Reid and Prof. F. G. Young), 903
Blood Group Antigen Jk^a (Human) : Inheritance of the (Dr. R. R. Race, Dr. Ruth Sanger, Dr. Fred H. Allen, jun., Dr. Louis Diamond and Bevely Niedziela), 207
ABO Blood Groups and Sex-Ratio at Birth in Man (Dr. L. D. Sanghvi), 1077
Blood Parasites of Mammals in New Zealand (Dr. M. Laird), 640
Blood Pigments (Respiratory) : Oxygen Affinities of, in *Serpula* (Prof. H. Munro Fox), 112
Blowfly Strike : A New Biological Method for Evaluating the Efficiency of Insecticides for the Protection of Sheep against (O. G. H. Fiedler and R. du Toit), 608
Blue Sun and Moon (Dr. William Paul and Prof. R. V. Jones), 545, 554 ; (R. R. Wilson), 545 ; (G. F. Lothian), 1086
Blue-Green Algæ (Nitrogen-fixing) : Effect of, on the Growth of Rice Plants (Dr. A. Watanabe, S. Nishigaki and C. Konishi), 748
Boar : Inositol, a Major Constituent of the Seminal Vesicle Secretion of the (Dr. T. Mann), 1043
Boards : The Men on the, a Study of the Composition of the Boards of Nationalised Industry (Acton Society Trust), 130
Body (Human) : Methylation of a Phenolic Hydroxyl Group in the (Prof. N. F. Maclagan and Dr. J. H. Wilkinson), 251
Body-Temperature of Small Insect Larvæ (F. L. Waterhouse), 340
Bone Phosphate : Renewal of, in Experimental Hyperparathyroidism (R. Zetterstrom and B. Engfeldt), 81
Books : Recent Scientific and Technical, Supp. iv, July 28 ; Supp. iv, August 25 ; Supp. vi, September 29 ; Supp. vi, October 27 ; Supp. vi, November 24 ; Supp. iv, December 29
Books across National Boundaries : Movements of, 437
Botanische Buchillustration (Claus Nissen), Band 1, Lieferung 1, and Band 2, Lieferung 1, *review* by Dr. W. B. Turrill, 848 ; Band 1, Lieferung 2, and Band 2, Lieferung 2, *review* by W. B. T., 1056
Botany : Medical (Dr. Alexander Nelson), *review* by G. E. H. Foxon, 262
Botany at Birmingham, 497
Bovine Tubercle Bacillus : Nature and Infectivity of Granular Forms of the (Dr. E. M. Brieger, Dr. J. A. R. Miles, Dr. V. E. Cosslett and R. W. Horne), 96
Boys (Charles Vernon) Prize for 1951 of the Physical Society awarded to Dr. J. H. E. Griffiths, 588
Bracon gelechiae Ashmead (Braconidae) : Effect of Hosts on the Egg Coloration of the Parasite (G. C. Sen Gupta), 793
Brain : Glucose, Glutamate and Succinate Oxidation in (Dr. H. Harris, Dr. E. M. Trautner and M. Messer), 914
Brain–Mind Problem : Hypotheses relating to the (Prof. J. C. Eccles), 53
Brains and Machines, *review* by Prof. S. Zuckerman, 1095
Brassica rapa, *Brassica oleracea* and *Beta vulgaris* : Occurrence of Antifungal Substances in (Dr. F. C. Gerretsen and Netty Haagsma), 659
Breeding of Pilchards off the West Coast of South Africa (Dr. C. Von Bonde and D. H. Davies), 952
Breeding Ground of Pilchards off the Coast of South-West Africa (Dr. T. J. Hart and N. B. Marshall), 272
Brick-Making : Research on, 331
Britain : Control of Broadcasting in, 667
  Early Celtic Metal-work in (Sir Cyril Fox), 229
  Insects and Hygiene in, *review* by Dr. V. B. Wigglesworth, 354
  The Land of (L. Dudley Stamp), second edition, *review* by Sir John Russell, 803
  A Natural History of Man in (Prof. H. J. Fleure), *review* by M. C. Burkitt, 757
  Planning the Land of, 967
  The Quail in (R. E. Moreau), 1114
  Spiders of, *review* by T. H. Savory, 714
  Wild Orchids of (V. S. Summerhayes), *review* by Prof. J. W. Heslop Harrison, 353
  The Wood Pigeon in (M. K. Colquhoun), 769
  See also under Great Britain
Britain Throughout the Ages : Man in, *review* by M. C. Burkitt, 757
Britain's Scientific Shrines (Eng.-Capt. Edgar C. Smith), (5), 180 ; (6), 443 ; *erratum*, 589 ; (7), 578
British Birds (F. W. Frohawk), *review* by Frances Pitt, 263
British Bulletin of Spectroscopy, 982
British Colonial Territories : Higher Education in, 591
  Research and Development in, 691
British Colonies : Geology and Mineral Resources in the (Prof. R. C. Dunham), 1109
British Colonies, 1950–51 : Research and Development in, 815
British Commonwealth and Empire Lecture of the Royal Aeronautical Society (Air Vice-Marshal Sir L. M. Isitt), 276
British Commonwealth Scientific Official Conference : Specialist Conference in Agriculture—Plant and Animal Nutrition in relation to Soil and Climatic Factors, Australia 1949, Proceedings, 499
British Commonwealth Scientific Official Conference to be held in Australia, 770
British Contribution to Science and Technology in the Past Hundred Years (H.R.H. the Duke of Edinburgh), 219
British Contribution to Television (Radio Section of the Institution of Electrical Engineers Convention on), 641
British Flora : Recent Research and Additions to the (J. E. Lousley), 934
British Freshwater Amphipoda : Distribution of (G. Fryer), 435
British Instrument Industries' Exhibition, 185
British Journal of Applied Physics (edited by Dr. H. R. Lang), Vol. 1, 1950, *review* by S. Weintroub, 7
British Land : Productivity of (Report of the Rural Reconstruction Association), 187
British Medicine and the Continent, 1600–1850 (Wellcome Historical Medical Museum Exhibition), 867
British Mysidacea (the late Prof. W. M. Tattersall and Olive S. Tattersall), *review* by Dr. W. T. Calman, 924
British Orchids, *review* by Prof. J. W. Heslop Harrison, 353
British Plastics Convention and Exhibition, 328
British Plastics Industry : Glossary of Terms used in the, 983
British Reservoirs : Silting in (R. M. Prothero), 27
British Spiders (G. H. Locket and Dr. A. F. Millidge), Vol. 1, *review* by T. H. Savory, 714
British Standard 628–32 (1950) and 650–56 (1950), Vegetable Oils, and 684 (1950), Methods of Analysis of Oils and Fats, 103 ; 1715 (1951), Methods for the Analysis of Soaps, 683 ; 1755 (1951), Glossary of Terms used in the Plastics Industry, 983
British Universities : Report of Proceedings of the 1950 Conference of, 18
British Varieties of Cereals, *review* by J. S. L. Waldie, 531
Broadcasting : Memorandum on the Report of the Broadcasting Committee 1949, 667
Broadcasting in Britain : Control of, 667
Broccoli Curd : Vegetative Propagation from the, after Suppression of Flowering (K. E. Haine), 919
Bromine Ions ? : Positive (Dr. F. Korosy and Gy. Székely), 77
2-Bromothiophene : Tetrabromothiophene from, by means of Sodium Acetylide in Liquid Ammonia (A. Vaitiekunas and Prof. F. F. Nord), 875
Bronze : Tarnish and Corrosion of Silver and, 639
Bronze in the Old World : Notes on the Prehistoric Metallurgy of Copper and (H. H. Coghlan), *review* by M. C. Burkitt, 531
Brood-Strength in the North Sea Haddock, in the Light of Relevant Wind Conditions : Variations in (Dr. J. N. Carruthers, Comdr. A. L. Lawford, Instructor-Lieut. V. F. C. Veley and B. B. Parrish), 317
Broom (Spanish) : Isolation of Octadecan-1 : 18-diol from (Dr. O. C. Musgrave, James Stark and Prof. F. S. Spring), 298
Brown Discoloration of Pig Fat and Vitamin E Deficiency (K. L. Robinson and W. E. Coey), 997
Bruce–Preller Lecture of the Royal Society of Edinburgh (Prof. E. L. Hirst), 61
Buffering Substances on Paper : A New Method for the Detection of Amino-Acids, Peptides, Proteins and other (Dr. J. Porath and P. Flodin), 202
Building Research Congress 1951, 975 ; Papers presented at the, 984
Buildings and Timber : The Protection of, against Termites (W. D. MacGregor and R. C. Fisher), 102
Bulletin of the Research Council of Israel, Vol. 1, Nos. 1–2, 188
Busk (Edward) Memorial Prize of the Royal Aeronautical Society awarded to R. Hills, 498
Butterfat : C[illegible] Unsaturated Acids of (Dr. F. B. Shorland and Miss D. L. Johannesson), 75 ; *erratum*, 899

CACAO : Application of an Incomplete Block Design to the Assessment of Quality in (J. A. R. MacLean and Robert Wickens), 434
Cadmium in Copper Alloys : Quantitative Chromatographic Separation and Estimation of, using Paper Strips (R. L. Davies), 834
Calcul dans des problèmes de mécanique : Méthodes de (Colloques Internationaux du Centre National de la Recherche Scientifique, 14), Marseille, 30 Mars–6 Avril 1948, Paris, 8–9 Avril 1948, *review* by H. T. H. P., 621
Calculus : Operational, based on the Two-Sided Laplace Integral (Dr. Balth van der Pol and Dr. H. Bremmer), *review* by J. H. Pearce, 133
Calibration of Geiger–Muller Liquid Counters by the Radioactivity of Potassium-40 (Dr. T. A. Chalmers), 870

Caliche and Archæological Materials : Radio-carbon Datability of Peat Marl, (H. H. Bartlett), 725
Calorimetry (Internal) : Physical Basis of (Dr. W. Chester and Dr. J. Grayson), 521
Cambial Injuries in a Pruned Stand of Norway Spruce (W. R. Day), 412
Camera in Antarctica (Alfred Saunders), *review* by Seton Gordon, 52
Canada 1951 : Physics in, 1067
Cancer, Where we Stand (Prof. Sidney Russ), *review* by Prof. J. S Mitchell, 802
Cancer : Applications of Physics in the Diagnosis and Treatment of (Physical Society Symposium on), 1023
  Chemistry of, 462
  Radiotherapy and, 101
Cancer for the Layman, *review* by Prof. J. S. Mitchell, 802
Cancer (Oral) : Researches on the Radiotherapy of (Constance A. P. Wood and J. W. Boag), 101
Cancer Research in Great Britain, 417
Canine Hepatitis Virus : Cultivation of, in Embryonated Hen's Eggs and its subsequent Transmission to Dogs (Dr. J. A. R. Miles, H. B. Parry, Dr. N. M. Larin and H. Platt), 699
Canine Hepatitis Virus and Antiserum for Serological Studies : Preparation of the Specific Purified Antigen of (Dr. N. M. Larin), 745
Canker Organism (Cherry Bacterial), *Pseudomonas mors-prunorum* Wormald : The Leaf Scar as an Avenue of Infection for the (J. E. Crosse), 560
Cape of Good Hope : Report of H.M. Astronomer at the, for the Year 1950, 1114
Capillaries : Physiology of the (Prof. H. P. Gilding), 230
Carbohydrate Primers for Q-Enzyme (S. A. Barker, A. Bebbington and Dr. E. J. Bourne), 834
Carbohydrates : Some Trithiocarbonate Derivatives of (G. P. McSweeney and Prof. L. P. Wiggins), 874
Carbon-labelled Benzene : A Convenient Synthesis of (H. S. Turner), 73
Carbon Dioxide : Effect of Irradiation by X-Rays on the Exhalation of, by the Mouse (Prof. G. Hevesy and A. Forssberg), 692
Carbon Dioxide (Solid) : Use of, in preparing a Cold Bath (L. G. E. Bell), 456
Carbon Isotopes in Carbonate Rocks : Relative Abundances of Oxygen and (Dr. P. Baertschi), 288
Carbon Monoxide : Formation of, in connexion with Hæmoglobin Catabolism (Torgny Sjostrand), 1118
Carbon Monoxide in Blood : The *in vitro* Formation and Disposal of (Torgny Sjostrand), 729
Carbon Tetrabromide Nature of the Transition in (Dr. J. G. Marshall, Dr. K. R. Hart and L. A. K. Staveley), 519
Carbon Tetrachloride · Effect of a Single Injection of, upon the Activity of the Pseudo-cholinesterase in the Liver and Serum of Male and Female Rats (Lucy M. Brown and Marion F. Harrison), 83
Carbon Tetrachlorides (Isotopic) : Vapour Pressure of (Prof. D. H. Rank and R. E. Kagarise), 740
Carbon-14 Method of Archæological Dating : Errors in the, 725
Carbon-14 and Tritium: Stimulation by Insulin of *in vitro* Fat Synthesis by Mammary Tissue studied with (Judith H. Balmain, Dr. S. J. Folley and Dr. R. F. Glascock), 1083
Carbon-14 Dioxide · Protein Synthesis in Nucleated and Non-nucleated Halves of *Acetabularia mediterranea* studied with (Prof. J. Brachet and Dr. H. Chantrenne), 950
C[illegible] Unsaturated Acids of Butterfat (Dr. F. B. Shorland and Miss D. L. Johannesson), 75 ; *erratum*, 899
Carbonate Rocks : Relative Abundances of Oxygen and Carbon Isotopes in (Dr. P. Baertschi), 288
Carborundum Crystals . Growth Mechanism of (S. Amelinckx), 431
  Growth Spirals on (Ajit Ram Verma), 430
  Growth Spiral Patterns on (Ajit Ram Verma), 783
Carboxyl Groups (Free) . Identification of the, in Peptides (J. Tibbs), 910
Carboxylic Acid Group in Cellulose : A Gravimetric Estimation of the (J. Farrar, Dr. S. M. Neale and G. R. Williamson), 566
Cardamine pratensis and *Nasturtium officinale* : The So-called Chromosome-Races of (Dr. H. W. Howard), 477 ; (Dr. G. Haskell), 478
Cartography of the Antarctic, 275
Castings : The Solidifications of (R. W. Ruddle), *review* by Prof. F. C. Thompson, 218
Cat's Tapetum . Spectral Reflexion Factor of the (R. Gunter, H. G. W. Harding and Dr. W. S. Stiles), 293
Catalysts (Nickel) . Activated Adsorption of Hydrogen on (Dr. G. C. A. Schuit and N. H. de Boer), 1040
Catalytic Conversion of a Diene into Deeply Coloured Polyenes (B. Eisler and Dr. A. Wassermann, Dr. F. D. Farnsworth, D. Kendrick and Dr. R. Schnurmann), 459
Cathode-Ray Tube Storage : Improvements in—Application to a Parallel Type of Digital Computer (G. H. Perry), 372
Cation Exchange and Clay Mineral Structure (Clay Minerals Group of the Mineralogical Society Discussion on), 107
Cationic Polymerization (University College of North Staffordshire Conference on), 545
Cattle : The Chillingham, 275
  Erythrocyte Antibodies as a Cause of Abortion in (J. Laing and F. Blakemore), 656
Cattle exposed to High Environmental Temperatures : Heat Tolerance of European Breeds of (J. Dobinson), 882
Cauliflower Mosaic Virus : Control of (J. G. Jenkinson and G. D. Glynne Jones), 336
Caulobacter versus *Bacillus* spec. div. (A. L. Houwink), 654
Cave Paintings in South Africa : Prehistoric (J. R. Harding), 275
Cavity Resonator Method for Electron Concentration in Flames (Dr. T. M. Sugden and B. A. Thrush), 703
Cell and Psyche (Edmund W. Sinnott), *review* by Prof. C. H. Waddington, 970
Cell Division : Chemistry of (Chemical Society, the Royal Institute of Chemistry, the Society of Chemical Industry and the Institute of Petroleum Discussion on), 462
  Formation of New Cell Walls in (Dr. Eveline Elliot), 1089
Cell Division in Mouse Epidermis : Deoxyribosenucleic Acid Synthesis during (Dr. W. S. Bullough and Dr. J. Pasteels), 608
Cell Physiology : Cytology and (edited by Geoffrey H. Bourne), second edition, *review*, 51
Cell Walls : Formation of New, in Cell Division (Dr. Eveline Elliot), 1089
Cells Walls (Yeast): Composition and Structure of (A. L. Houwink, D. R. Kreger and P. A. Roelofsen), 693
Cells Surface, of Feather Barbs (L. Auber and H. M. Appleyard), 736
Cells (Bacterial) : Variation with Age in the Resistance of (Dr. Helen R. White), 828
Cells (Living) : Action of, on Cortisone Acetate Crystals (Dr. A. Stafford Steen), 652
Cellulase of *Myrothecium verrucaria* : Purification of the (D. R. Whitaker), 1070
Cellulose : A Gravimetric Estimation of the Carboxylic Acid Group in (J. Farrar, Dr. S. M. Neale and G. R. Williamson), 566
α-Cellulose : Digestion of, by Larvæ of *Anobium punctatum* De Geer (D. Spiller), 209
Cellulosic Solutions (Viscose) : Effects of Ultrasonic Irradiation on the Coagulation of (Dr. V. Tomberg), 292
Celtic Metal-work in Britain : Early (Sir Cyril Fox), 229
Cement Block, an Improved Block for Spore-formation in Yeast (V. Hartelius and E. Ditlevsen), 385
Census 1951, England and Wales : Preliminary Report (General Register Office), 580
Centenary of Section E (Geography) of the British Association for the Advancement of Science (Dr. O. J. R. Howarth), 227
Centralization : The Extent of—a Discussion based on a Case Study in the Coal Industry, 842
  The Extent of (Acton Society Trust, National Industry Series 6 and 7), 982
Century of Physics, 622
Cerastium Species Chromosome Numbers of (Olive E. Brett), 793
Cereal Varieties in Great Britain (R. A. Peachey), *review* by J. S. L. Waldie, 531
Cestodes : Egg-Shell Formation in Trematodes and, as demonstrated by the Methyl or Malachite Green Techniques (Dr. J. D. Smyth), 322
Ceylon : Cultural Anthropology of the Rodiyas of, 813
Chain Folding in Synthetic Polypeptides and Gelatin : Optical Rotation and (Dr. Conmar Robinson and M. J. Bott), 325
Charge-Renormalization accompanying Radiative Corrections (M. Demeur), 1037
Chemical Bond : Structure of Molecules and the (Y. K. Syrkin and M. E. Dyatkina), translated and revised by M. A. Partridge and D. O. Jordan, *review* by Prof. M. J. S. Dewar, 970
Chemical Composition of Stratosphere Air · Variations in the (Dr. K. F. Chackett, Prof. F. A. Paneth, P. Reasbeck and B. S. Wiborg), 358
Chemical Effects in Liquids due to α-Particle Irradiation (Prof. P. I. Dee and E. W. T. Richards), 736
Chemical Engineering : Scheme for a Part-time Course in (Institution of Chemical Engineers), 1104
Chemical Industry . The Changing Face of (British Association, Section B (Chemistry), Discussion on), 502
  Safety and Hygiene in, from the Point of View of the Manager, Technician and Operative (Sindicato Vertical de Industrias Quimicas Conference on), 641
Chemical Literature : A Short Guide to (Dr. G. Malcolm Dyson), *review*, 355
Chemical Research : Ramsay Memorial Fellowships for, 983
Chemical Shortages and the Efficient Use of Processing Solutions (Scientific and Technical Group of the Royal Photographic Society and the British Kinematograph Society Symposium on), 103
Chemical Technology (Library Association Reader's Guides, New Series, No. 9), 103
Chemical-Biological Correlation (Chemical-Biological Coordination Center of the National Research Council second Symposium on), 456
Chemicals in Food (Dr. Francis Aylward), 778
  Problems arising from the use of (Food, Agriculture and Fine Chemicals Groups of the Society of Chemical Industry Conference on), 236
Chemie (Organischen) : Synthetische Methoden der (W. Theilheimer), Repertorium 3, *review*, 262
Chemie in kurzgefasster Darstellung : Geschichte der (Prof. Dr. Georg Lockemann), Band I, *review* by J. R. P., 716
Chemie der Phenolharze (Dr. K. Hultzsch), *review* by N. J. L. Megson, 215
Chemisorbed Film : Influence of a, on Subsequent Physical Absorption Processes (A S. Joy and T. A. Dorling), 433 ; (P. F. Tiley), 434
Chemistry : The Application of Statistical Methods to (London and South Eastern Counties Section of the Royal Institute of Chemistry Discussion on), 1072
  The Colloid, of the Silicate Minerals (Prof. C. Edmund Marshall), *review*, 577
  An Eighteenth Century Lectureship in (edited by Dr. Andrew Kent), *review* by L. P. Gilbert, 969
  Fluorine (edited by Dr. J. H. Simons), Vol. I, *review* by Dr. H. A. Skinner, 621
  A Hundred Years of (Lord McGowan), 369
  Intermediate Practical (Sylvanus J. Smith), *review*, 399
  Medicinal (Prof. Alfred Burger), Vol. I, *review* by Prof. J. W. Cook, 438
  Organic, in the Service of Medicine (British Association, Section B (Chemistry), Symposium on), 402
  Advanced Organic (Prof. Reynold C. Fuson), *review* by Dr. R. A. Raphael, 262
  Physical (A. J. Mee), fourth edition, *review* by G. Fowles, 399
  Physical (Prof. Walter J. Moore), *review* by G. F., 577
  Physical—Experimental and Theoretical (Dr. G. Van Praagh), *review* by G. Fowles, 1056
  Pure and Applied, of Acridine Compounds, *review* by Dr. J. Walker, 713
  Pure and Applied, of Starch, *review* by Prof. R. H. Hopkins, 179
  Structural, of Inorganic Compounds (Prof. Walter Huckel), translated by Dr. L. H. Long, Vol. I, *review* by Prof. E. G. Cox, 756
  Structural Inorganic (A. F. Wells), second edition, *review* by Prof. E. G. Cox, 756
Chemistry (Analytical) : International Congress on, 368
Chemistry (Applied): Dictionary of (Thorpe's), fourth edition, Vol. 10, *review* by Prof. R. P. Linstead, 716
Chemistry (Biophysical) : Progress in Biophysics and (edited by Dr. J. A. V. Butler and Prof. J. T. Randall), *review* by Dr. D. P. Riley, 532
Chemistry (Colloid) : The Teaching of, *review* by Dr. D. P. Riley, 132

Chemistry (Inorganic and Physical) Trend of, since 1850 (Prof. F. A. Paneth), 371
Chemistry (International) : The American Chemical Society and (Sir Eric K. Rideal), 765
Chemistry (Lichen) : Japanese Monograph of, *review* by Dr. J. C. Dacre, 889
Chemistry (Organic) : Electronic Theories of, *review* by Dr J. W. Baker, 92
  Elsevier's Encyclopaedia of (edited by F. Radt), Series 3, Carboisocyclic Condensed Compounds, Vol. 12B, Naphthalene, A, Compounds containing One Naphthalene Nucleus ; Oxo-Compounds (except Quinones), *review* by Prof. J. W. Cook, 218
  A Hundred Years of, (1851–1951), (Prof. A. R. Todd), 326
  Physical Aspects of (Dr. William A. Waters), fourth edition, *review* by Dr. J. W. Baker, 92
Chemistry (Organic Fluorine) : Recent Advances in (Dr. R. N. Haszeldine), 1028
Chemistry (Physical) : Annual Review of (edited by G. K. Rollefson and R E. Powell), Vol. I, *review* by Dr. H. A. Skinner, 716
  The Structure of (Sir Cyril Hinshelwood), *review* by Prof. M. G. Evans, 712
  The Teaching of, *review* by Prof. M. G. Evans, 712
Chemistry (Pure and Applied) : Twelfth International Congress of (D. Hamer), 766
Chemistry (Pure and Applied), Reviews of (Royal Australian Chemical Institute), First issue, 188
Chemistry at Queen Mary College, London, 319
Chemistry at the University of Sydney—Gift for New Building, 110
Chemistry of Alkaloids : The Technology and (Frank E. Hamerslag), *review*, 311
Chemistry of Cancer, 462
Chemistry of Cell Division (Chemical Society, the Royal Institute of Chemistry, the Society of Chemical Industry and the Institute of Petroleum Discussion on), 462
Chemistry of the Earth, *review* by Prof. K. C. Dunham, 843
Chemistry of Heterocyclic Compounds, *review* by Dr. James D. Loudon, 618
Chemistry of Lichen Substances (Prof. Yasuhiko Asahina and Prof. Shoji Shibata), *review* by Dr. J. C Dacre, 889
Chemistry at the Mid-Century (Sir Cyril Hinshelwood), 226
Chemistry of the Oxidative Metabolism of certain Aromatic Compounds by Micro-organisms (Dr. W. Charles Evans, B. S. W. Smith, Prof. R. P. Linstead and Dr. J. A. Elvidge), 772
Chemistry of Phenolic Resins, *review* by N. J. L. Megson, 215
Chemistry and Bacteriology of Silage (Society for Applied Bacteriology Symposium on), 730
Chemistry and Industry of Starch (edited by Dr. Ralph W. Kerr), second edition, *review* by Prof. R. H. Hopkins, 179
Chemistry and Physiology of the Nucleus (Brookhaven National Laboratory Conference on), 189
Chemistry and Technology of Metals and Alloys, 414
Chemists · Glasgow, *review* by L. F. Gilbert, 969
Chemotherapeutic Agents to Chick Embryos : A Method for Administering (L. H. Collier), 832
Chemotherapeutic Substances : The Evaluation of (Biological Methods Group of the Society of Public Analysts and other Analytical Chemists Symposium on), 865
Chemotherapy Work : Use of a Sheep Abortion Virus as a Test Virus for (Dr. Lois Dickinson and G. W. Inkley), 37
Chemotherapy of Tuberculosis (Medical Research Council of Ireland Symposium on), 539
Cherry Bacterial Canker Organism, *Pseudomonas mors-prunorum* Wormald : The Leaf Scar as an Avenue of Infection for the (J. E. Crosse), 560
Chestnut Blight (Forestry Commission Booklet No. 3), 412
χ^2 : Calculation of, for a 2 × 2 Table (Dr. B. Woolf), 1087
Chick : Transfer of Bacterial Antibodies from the Hen to the (A. Buxton), 657
Chick Embryo Membrane Infected with *PR-8* Influenza : Electron Microscopy of (Dr. Ralph W. G. Wyckoff), 651
Chick Embryos : A Method for Administering Chemotherapeutic Agents to (L. H. Collier), 832
  Stimulation of Bile Secretion in, by Cortisone (M. M. Mosbaugh and Prof. A. W. Ham), 789
Chicks . Mode of Action of Antibiotics in Stimulating Growth of (M. E. Coates, C. D. Dickinson, G. F. Harrison, Dr. S. K. Kon, Sheila H. Cummins and W. F. J. Cuthbertson), 332
Children Out of School (Joy C. Ward), 649
Children's Leisure, 649
Chillingham Cattle · The, 275
Chimie et de la physique des molécules géantes : Etat actuel de la (Prof. H. Mark, avec la collaboration de Prof. T. Alfrey et Prof. R. B. Mesrobian), *review* by Dr. D. P. Riley, 355
Chlamydomonas · Effect of *cis*-Cinnamic Acid and some Isomeric Compounds on the Germination of Zygotes of (Prof. Franz Moewus and Basudev Banerjee), 561
Chloride from Mammalian Skin : Extraction of (Dr. M. Grace Eggleton), 660
Chloromycetin : Action of Terramycin and, on Cholera Vibrio in Mice (Dr. E. Olejnik and S. Davidovitch), 654
Chlorophyll Inhibition and Growth Regulation by several Tetronic Acid Derivatives (J. Alamercery, Dr. C. L. Hamner and M. Latus), 85
Chlorosaccus ulvaceus Massik. and Vischer (Dr. E. A. Fliat), 999
Cholera Vibrio in Mice : Action of Terramycin and Chloromycetin on (Dr. E. Olejnik and S. Davidovitch), 654
Cholinesterase Activity in the Secretions of the Pancreas of the Dog and Parotid of the Pig (Prof. R. A. McCance, L. M. Brown, Dr. R. S. Comline and D. A. Titchen), 788
Cholinesterase Inhibition by Parathion *in vivo* (W. M. Diggle and J. C. Gage), 998
Christian Challenge to Philosophy (the late W. H. V. Reade), *review* by F. I. G. Rawlins, 178
Christianity and Human Relations in Industry (Sir George Schuster), 842
Christmas Lectures for Juveniles, 984
Chromatograms (Amino-acid) : Conservation of (Dr. E. Kawerau and Prof. T. Wieland), 77
Chromatograms (Paper) : A Colour Reaction distinguishing between Adrenaline and *nor*-Adrenaline on (Dr. A. J. Glazko and W. A. Dill), 32
  Detection of Deoxyribonucleosides on (Dr. J. G. Buchanan), 1091
  Identification of Sulphonamides on (Alan E. Steel), 877
Chromatographic Analysis of Amino-Acids of Molasses and other Beet-sugar Industry By-products (Eugenio Mariani and Giorgio Torraca), 959
Chromatographic Detection of Pyruvic, Dimethylpyruvic and α-Ketoglutaric Acids in Cultures of *Aspergillus niger* on various Substrates (Dr. T. K. Walker, A. N. Hall and J. W. Hopton), 1042
Chromatographic Evidence for the Tetraphosphate Ion (Dr. A. E. R. Westman and A. E. Scott), 740
Chromatographic Separation and Estimation of Cadmium in Copper Alloys using Paper Strips : Quantitative (R L. Davies), 834
Chromatography Paper, of Flax Fibre Polyuronide Hemicellulose (G. C. Whiting), 833
  Paper, of Muscle Tissue Constituents—Paper Chromatography of Adenosine Phosphates (Dr. Olle Snellman and Dr. Bertil Gelotte), 461 ; A Phosphate-absorbing Protein from Muscular Tissue (Dr. Bertil Gelotte), 461 , The Prosthetic Group of Actin (Dr. Olle Snellman and Dr. Bertil Gelotte), 462
  Paper, of Nicotinic Acid Derivatives (Dr. E. Kodicek and K K. Reddi), 475
  Paper, of the Pyrogallol Tannins (R. S. Asquith), 738
  Paper Partition, of Alcohols using the Potassium Xanthogenates (Tatsuo Kariyone, Dr. Yohei Hashimoto and Mutsuo Kimura), 511
  Paper Partition, of some Organic Bases by the method of N-Methylation (Tatsuo Kariyone and Dr. Yohei Hashimoto), 739
  Partition Paper, of some Organic Acids (Prof J. Opienska-Blauth, O. Saldewska-Szymonowa and M. Kanski), 511
  Quantitative Paper (H. D. Fowler), 1123
Chromatography (Adsorption) . A Simplified Coupled Filter System for (Dr. David A. Hall), 124
Chromatography (Paper) : Colour Reagents for the, of Di- and Tri-hydroxy Phenols (D. G. Roux), 1041
  Detection of Enzymes by the Agar-Plate Method and its Application to (W. W. Reid), 739
  Detection of Sugars by (R. J. Bayly, Dr. E. J. Bourne and Prof. M. Stacey), 510
  Separation of Enzymes by (Prof. K. V. Giri and A. L. N. Prasad), 786
  Effect of Temperature on the R_F Values of the Amino-acids during, with Solvents completely Miscible with Water (D. P. Burma), 565
  Estimation of Volatile Fatty Acids and Ammonia in Silage by means of (Prof. Artturi I. Virtanen and Jorma K. Miettinen), 294
  Separation of Alkaloids by (J. E. Carless and H B. Woodhead), 203
Chromatography (Paper Partition) : Application of Buffered Solvent Systems to the Detection of Aromatic Acids by (Mona E. Fewster and Dr David A. Hall), 78
  Identification of Sulphonamides by (R. Robinson), 512
  A Rapid Method for the Determination of Nucleic Acid Components by (Jan-Erik Edstrom), 876
Chromatography of Adrenotropic Hormone on Ion-exchange Columns (H. B. F. Dixon, Dr. Stanford Moore, M. P. Stack-Dunne and Prof. F. G. Young), 1044
Chromatography of Mixtures of Amino-acids containing Cysteine : Artefacts in the (M. B. Van Halteren), 1090
Chromatography Solvent · A New Paper, for Amino-Acids (F. Bryant and B. T Overell), 167
Chromatography and Fluorescence · Determination of Sodium Gentisate by (Dr. L. Nanninga and B. Bink), 389
Chromic Acid : Course of the Oxidation of Olefins by (Dr. W. J. Hickinbottom and D. G. M. Wood), 33
Chromium, Vanadium and Molybdenum : Radiochemical Determination of, by means of Radioactive Silver (Dr. J. Goverts and Carlos Barcia-Goyanes), 198
Chromium Phosphate (Radioactive) : Effect of Antihistamine on the Reticulo-endothelial System—Investigation of Reticulo-endothelial Function with the aid of (Dr. Elemér R. Gabrieli), 467
Chromium–Aluminium Oxide Catalyst System : Activity of the, in the Nitrile-Diene and *n*-Heptane Cyclizations (Dr. G J. Janz and P. J. Hawkins), 387
Cr_2O_3 near the Curie Temperature : Changes in Lattice Constants of (Miss Selma Greenwald), 379
Chromosome of the House Mouse . A Pronounced Sex Difference in Recombination Values in the Sixth (S. A. Mallyon), 118
Chromosome Elimination in *Saccharum* (Dr. N. Parthasarathy), 383
Chromosome Morphology in *Helicophyllum crassipes* : Chromosome Number and (Miss Teoraya Lotfy), 338
Chromosome Number An Isopod, *Asellus meridianus* Racovitza, with Low (S. Muldal), 1127
Chromosome Number and Chromosome Morphology in *Helicophyllum crassipes* (Miss Teoraya Lotfy), 338
Chromosome Numbers of *Cerastium* Species (Olive E. Brett), 793
Chromosome-Races of *Cardamine pratensis* and *Nasturtium officinale* . The So-called (Dr. H. W. Howard), 477 ; (Dr. G. Haskell), 478
Chromosomes in Yeasts (Dr. M. K. Subramaniam), 427
Chromyl Chloride and Chromyl Fluoride : Lamellar Compounds of Graphite with (R. C. Croft and R. G. Thomas), 32
Chromyl Fluoride . Lamellar Compounds of Graphite with Chromyl Chloride and (R. C. Croft and R. G. Thomas), 32
Chubb Crater in Northern Canada (National Geographic Society and the Royal Ontario Museum, Toronto, Joint Expedition to), 145
cis-Cinnamic Acid and some Isomeric Compounds : Effect of, on the Germination of Zygotes of *Chlamydomonas* (Prof. Franz Moewus and Basudev Banerjee), 561
Circularly Polarized γ-Rays and the Production of Polarized Electrons : Detection of (Prof. Otto Halpern), 782
Citrate Levels . Kidney, in Nucleotide Shock (C. J. Threlfall, H. B. Stoner and Prof. H. N. Green), 297
Citrullus · Urease Metabolism in (Dr. W. T. Williams and P. Ch. Sharma), 659
Civil Administration in Great Britain, *review* by R. Brightman, 310
Civil Defence : Scientific Advisers for, 984
Civil Engineering at Adelaide, 1066
Civil Rights : Academic Freedom and, 1051

Civil Service Today: The (T. A. Critchley), *review* by R. Brightman, 310
Civilian Field: Government Scientific Organization in the, 482
Clams (Soft- and Hard-shell): Vitamin B_{12} Content of (Prof. Bernard E. Proctor and David A. Lang), 36; *erratum*, 63
Clathrate Compounds: Structure of (H. M. Powell), 11
Clay Mineral Structure: Cation Exchange and (Clay Minerals Group of the Mineralogical Society Discussion on), 107
Clay Minerals with a Fibrous or Rod-like Habit: Electron Diffraction by (D. R. Kaapp and Dr. R. P. Mitra), 380
Clayton Awards for 1951 of the Institution of Mechanical Engineers, 236
Climate: The Scenery of Devonshire in relation to Weather and (L. C. W. Bonacina), 1105
  Time and, *review* by Dr. E. C. Bullard, 48
Climatic Change in North Europe about A.D. 1300: Archaeological Dating of the (Dr. Axel Steensberg), 672
Climatic Conditions in the Sea as exemplified by the English Channel: Influences of Tidal Streams on Oceanographic and (Dr. G. Dietrich), 8
Climatic Factors: Plant and Animal Nutrition in relation to Soil and (British Commonwealth Scientific Official Conference: Specialist Conference in Agriculture, Australia 1949, Proceedings), 499
Climatic Variations in Indonesia: Recent (K. J. ten Hoopen and Dr. F. H. Schmidt), 428
Clock Paradox in Relativity Theory (Dr. Herbert E. Ives), 246
Cloud Scenery · London's Picturesque (L. C. W. Bonacina), 1105
Clouds (Luminous Night): Auroras and (J. Paton), 487
Clover: Nitrogen Nutrition of (J. T. Vantsis and Dr. G. Bond), 339
Clover Plants: Multiple Infection of, by Strains of the Nodule Organism in the Field (Kathleen K. Baird), 116
Coagulation of Cellulosic Solutions (Viscose): Effects of Ultrasonic Irradiation on the (Dr. V. Tomberg), 292
Coal · Adsorption on (Dr. G. Garrod Thomas), 474
  Adsorption of Water and Methanol on (J. A. Lecky, W. Keith Hall and Robert B. Anderson), 124
  History of, 899
Coal Industry: The Extent of Centralization—a Discussion based on a Case Study in the, 842
Coal Industry of Great Britain, 982
Coal Tar: Isolation of 2:3:4:6-Tetramethylpyridine from (H. B. Nisbet and A. M. Pryde), 832
Coalminers in South Wales: The Social Consequences of Pneumoconiosis among (Dr. P. Hugh-Jones and Dr. C. M. Fletcher), 1106
Coastal Engineering (Southwest Research Institute, San Antonio, Texas, in co-operation with the University of California, Texas A. and M. Research Foundation, Rice Institute, University of Houston, and the Houston Branch of the American Society of Civil Engineers, second Conference on), 456
Cobalt-60 Nuclei (Oriented): An Experiment on Nuclear Alignment—the Anisotropy of γ-Radiation from (J. M. Daniels, Dr. M. A. Grace and F. N. H. Robinson), 780
Cobalt-60 Units for Radiation Therapy: 1,000-Curie (Dr. H. E. Johns, L. M. Bates, E. R. Epp, D. V. Cormack, S. O. Fedoruk, A. Morrison, W. R. Dixon and C. Garrett), 1035
Cocarboxylase in Experimental Diabetes (Dr. D. Silliprandi and N. Silliprandi), 422
Coconuts: An Insect Pest of, and its relation to certain Ant Species (M. J. Way), 302
Coenzyme of Kidney Phosphatase (Prof. M. Lora Tamayo and A. M. Municio), 249
Cohesive Energy of Metallic Beryllium: A New Calculation of the (B. Donovan), 836
Coins: Ancient Greek Plated (Prof. F. C. Thompson and A. K. Chatterjee), 158
Colchicine: Bacterial Enzyme Preparations oxidizing Inositol and their Inhibition by (Robert E. Franzl and Prof. Erwin Chargaff), 955
Cold on Micro-Organisms: Effect of (Society for Applied Bacteriology Symposium on), 990
Cold-working at Liquid-Air Temperature: Change of Resistivity of Gold by, and its Recovery by Temporary Heating (Prof. M. J. Druyvesteyn and J. A. Manintveld), 868
Collagen: Free Amino Groups of (J. H. Bowes and J. A. Moss), 514
Collembola: Keys and Bibliography to the (J. T. Salmon), 640
Colloid Chemistry: The Teaching of, *review* by Dr. D. P. Riley, 132
Colloid Chemistry of the Silicate Minerals (Prof. C. Edmund Marshall), *review*, 577
Colloid Science (edited by Prof. H. R. Kruyt), Vol. 2, *review* by Dr. A. S. C. Lawrence, 800
  Advances in (edited by Prof. H. Mark and E. J. W. Verwey), Vol. 3, *review*, 1016
Colloids (Hydrophilic): A Fast Continuous Electrodialyser for, and a Fast Continuous Electrodecanter for Hydrophobic Colloids (Prof. A. J. Rutgers and R. Swyngedouw), 727
Colloids (Hydrophobic): A Fast Continuous Electrodialyser for Hydrophilic Colloids, and a Fast Continuous Electrodecanter for (Prof. A. J. Rutgers and R. Swyngedouw), 727
Colonial Raw Materials: The Processing of (Charlotte Leubuscher), 1105
Colonial Research 1950–51 (Colonial Office), 815
Colonial Resources: Development of, 1
Colonial Territories 1950–51; The, 591
Colonial Territories (British): Higher Education in, 591
  Research and Development in, 691
Colonies: Education in the, 393
Colonies (British): Geology and Mineral Resources in the (Prof. R. C. Dunham), 1109
Colonies (British), 1950–51: Research and Development in, 815
Colorimetric Method for the Determination of Sugars (M. Dubois, K. Gilles, J. K. Hamilton, P. A. Rebers and Prof. F. Smith), 167
Colour Reaction distinguishing between Adrenaline and nor-Adrenaline on Paper Chromatograms (Dr. A. J. Glazko and W. A. Dill), 32
Colour Reagents for the Paper Chromatography of Di- and Tri-hydroxy Phenols (D. G. Roux), 1041
Colour Sensitivity of the Eye: Changes in, with Posture (Dr. J. N. Aldington), 86; (A. Blackie), 524; (F. Taylor), 524
Colour Vision of an Albino (Dr. R. W. Pickford), 954
Colours and How to See Them (Dr. H. Hartridge), *review* by J. Guild, 51
Commonwealth Index of Scientific Translations, 215
Commonwealth Postgraduate Scholarships in Science, 938
Commonwealth Scientific Official Conference, British: Specialist Conference in Agriculture—Plant and Animal Nutrition in relation to Soil and Climatic Factors, Australia 1949, Proceedings, 499
Commonwealth Scientific Official Conference, British: To be held in Australia, 770
Communications: World—The Impact of Speed (British Association (Division for Social and International Relations of Science), Discussion on), 446
Complement Fixing Antigen in T5 *coli* Bacteriophage (Phyllis M. Rountree), 34
Complexity: Unity and, *review* by F. I. G. Rawlins, 574
Composition and Structure of Yeast Cell Walls (A. L. Houwink, D. R. Kreger and P. A. Roelofsen), 693
Compounds (Optically Active): Determination of the Absolute Configuration of, by means of X-Rays (Prof. J. M. Bijvoet, A. F. Peerdeman and A. J. van Bommel), 271
Compounds showing Intramolecular Overcrowding: X-Ray Crystallographic Measurements on some (E. Harnik, F. H. Herbstein and G. M. J. Schmidt), 158
Compressibilities of Cubic Crystalline Powders—a New Method of Measurement (Prof. S. Bhagavantam and T. Seshagiri Rao), 744
Compton and other Incoherent X-Ray Scattering in Crystals: A New Method of Observing (H. J. Grenville-Wells), 291
Computer (Digital): Improvements in Cathode-Ray Tube Storage—Application to a Parallel Type of (G. H. Perry), 372
Computing Machine at the University of Manchester: The New Universal Digital (Dr. T. Kilburn), 95
Cone Electroretinography by Flicker (Dr. E. Dodt), 738
Configuration of Optically Active Compounds: Determination of the Absolute, by means of X-Rays (Prof. J. M. Bijvoet, A. F. Peerdeman and A. J. van Bommel), 271
Configurations of Polypeptide Chains (Prof. Linus Pauling and Prof. Robert B. Corey), 550
Conifer Tracheids: Helical Thickenings and Micellar Orientation in the Secondary Wall of (Dr. A. B. Wardrop and H. E. Dadswell), 610
Conservation in South Africa: Forestry and, 726
Contamination of Evaporated Films by the Supporting Material of the Source (O. S. Heavens), 664
Continent: British Medicine and the, 1600–1850 (Wellcome Historical Medical Museum Exhibition), 867
Control: Automatic (Department of Scientific and Industrial Research Conference on), 404
Convergence: Adaptation in Rodent Moles and Insectivorous Moles, and the Theory of (Dr. G. Eloff), 1001
Copley Medal for 1951 of the Royal Society awarded to Prof. D. Keilin, 856, 1017
Copper: Mechanical Properties of α-Solid Solutions of, with Zinc, Gallium, Germanium and Arsenic (Dr. N. P. Allen, T. H. Schofield and A. E. L. Tate), 378
Copper in Solution: Toxicity of, to the Stone-loach (P. J. Mackereth and W. J. P. Smyly), 1120
Copper Alloys: Quantitative Chromatographic Separation and Estimation of Cadmium in, using Paper Strips (R. L. Davies), 834
$Cu_{[illegible]}Al_{[illegible]}$: Structure of (Dr. A. J. Bradley), 661
Copper Sulphate: Prevention of Swayback Symptoms in Lambs by administration of, to the Pregnant Ewe (Dr. George Dunlop), 728
Copper and Bronze in the Old World: Notes on the Prehistoric Metallurgy of (H. H. Coghlan), *review* by M. C. Burkitt, 531
Copyright and Industrial Designs (A. D. Russell-Clarke), *review* by R. G. Lloyd, 847
  Law of, *review* by R. G. Lloyd, 847
Corneal Epithelium of Rabbits: Electric Shock and the Regeneration of the (Margarete Holzbauer and Prof. R. Rigler), 919
Cornish Coast (North): Prehistoric Sites on the (Joan R. Harding), 589
Corona: Negative Point-to-Plane—a New Mode of Discharge (Allan Greenwood), 41
  Pre-Breakdown Discharges in D.C. Positive Point-to-Plane (H. M. Gaunt and Dr. J. D. Craggs), 859
Corpora amylacea in the Central Nervous System (J. Molnar), 39
Correlation between Male and Female Elements in Fertilization: Activation and the (C. R. Austin), 558
Corrosion: Preservation of Glass from (Max Unwin), 215
Corrosion (Wet): Dry Oxidation and (Dr. U. R. Evans), 853
Corrosion of Buried Metals (Iron and Steel Institute, in conjunction with the British Iron and Steel Research Association and the Corrosion Group of the Society of Chemical Industry, Symposium on), 456
Corrosion of Silver and Bronze: Tarnish and, 639
Corrosion by Sulphate-reducing Bacteria: Iron/Sulphide Ratios in (C. J. P. Spruit and J. N. Wanklyn), 951
Cortical Hormones from *allo*Steroids—Synthesis of Cortisone from Reichstein's Compound *D* (Dr. G. Rosenkranz, Dr. Carl Djerassi, R. Yashin and J. Pataki), 28
Cortisone: Stimulation of Bile Secretion in Chick Embryos by (M. M. Mosbaugh and Prof. A. W. Ham), 789
Cortisone from Reichstein's Compound *D* · Cortical Hormones from *allo*Steroids—Synthesis of (Dr. G. Rosenkranz, Dr. Carl Djerassi, R. Yashin and J. Pataki), 28
Cortisone Acetate Crystals: Action of Living Cells on (Dr. A. Stafford Steen), 652
Cosmic Radiation: Recent Advances in the Study of (Dublin Institute of Advanced Studies Colloquium on), 236
Cosmic Ray Neutrons in Photographic Emulsions: Nuclear Disintegrations Caused by Fast (Dr. J. Pernegr), 1005
Cosmic Ray Observatory at Ottawa (Dr. D. C. Rose), 269
Count: Ability of Birds to (Prof. O. Koehler), 373
Countries (Under-developed): United Nations Technical Assistance to, 544
Crayfish *Jasus lalandii* (Milne Edwards): A Study of the Marine Spiny (C. A. Bradstock), 640
Creep Curves of Metals: Formula for (Prof. Ryukiti Robert Hasiguti and Tosiro Owadano), 706; (Prof. E. N. da C. Andrade), 1007
Crop Response to Phosphate in Acid Soils. Relationship between Base Saturation and (Dr. H. F. Birch), 388
Cromarty: Nature Reserve in Ross and, 938
Cross (Dorothy Temple) Research Travelling Fellowships in Tuberculosis (Medical Research Council Awards), 189

Cross-wind : Effect of, on a Projectile (K. Pennycuick), 41
Crotoxin : Amino-acid Composition of (Dr. K. H. Slotta and J. Primosigh), 696
'Crude Fibre' : Effect of Altitude on the Estimation of (J. R. Todd), 76
Crustal Layers of the Earth (Prof. A. L. Hales), 163 ; (P. L. Willmore), 164
Crystal Habit of Inorganic Salts : Modification of, with Dyes (Dr. J. Whetstone), 663
Crystal Spacings of Binary Fatty-acid Mixtures : Solidification Curves and (M. Fieldes and L. Hartman), 74
Crystal Structure of Ergine (J. L. DeVries and Prof. R. Pepinsky), 431
Crystal Structure of a Low Molecular Weight Protein—Electron Microscopy of β-Lactoglobulin Crystals (Dr. L. M. Dawson), 241 ; Structure of Dry β-Lactoglobulin Crystals (Dr. D. P. Riley), 242
Crystal Structure of 'Quinaldil' (D. R. Davies and H. M. Powell), 386
Crystalline Powders (Cubic) : Compressibilities of—a New Method of Measurement (Prof. S. Bhagavantam and T. Seshagiri Rao), 744
Crystallization of the α-Amylase of *Aspergillus oryzae* (Dr. Ed. H. Fischer and R. de Montmollin), 606
Crystallography (X-Ray) : Aspects of, *review* by Dr. H. Lipson, 576
  Selected Topics in, from the Delft X-Ray Institutes (edited by J. Bouman), *review* by Dr. H. Lipson, 576
Crystals : A New Method of Observing Compton and other Incoherent X-Ray Scattering in (H. J. Grenville-Wells), 291
Crystals (Dielectric) : Thermal Conductivity of—The 'Umklapp' Process (Dr. R. Berman, Prof. F. E. Simon and Dr. J. Wilks), 277
Ctenophore (Platyctenid) : A New, from Jamaica (Jessie J. Rankin), 1047
Cube-Edges of Uraninites as a Criterion of Age ? (B. Wasserstein), 380
Cubic Crystalline Powders : Compressibilities of—a New Method of Measurement (Prof. S. Bhagavantam and T. Seshagiri Rao), 744
Culex (Culex) torrentium Martini, a Mosquito New to Great Britain (P. F. Mattingly), 172
Cultivation of Sugar-cane : Intraseasonal Growth Variation and (Dr. C. V. Krishna Iyengar), 252
Cumacés (Prof. Louis Fage), *review*, 1056
Curie Temperature : Changes in Lattice Constants of Cr_2O_3 near the (Miss Selma Greenwald), 379
Cybernetics and Society : The Human Use of Human Beings—(Prof. Norbert Wiener), *review* by F. I. G. Rawlins, 442
Cystine : Artefacts in the Chromatography of Mixtures of Amino-acids containing (M. B. Van Halteren), 1090
Cytology (Bacterial) : Elements of (Prof. Georges Knaysi), second edition, *review* by Dr. K. A. Bisset, 439
Cytology of the Ecotypes of Dioecious *Melandrium dioicum* (L. emend.) Coss & Germ. (Dr. H. G. Baker and W. Jackson), 747
Cytology and Cell Physiology (edited by Geoffrey H. Bourne), second edition, *review*, 51

DAIRY Bacteriology : Practical (Prof. Paul R. Elliker), *review*, 621
Dalton Lecture (Lord McGowan), 369
Dangers Attendant on the Use of N-Halogenamides in Organic Reactions (Prof. R. H. Martin), 32
Daphnia magna : A Case of Disturbed Metabolism in (Edw. Flückiger), 211
Dating the Past (Prof. Frederick E. Zeuner), second edition, *review* by Dr. E. C. Bullard, 48
Davy Medal for 1951 of the Royal Society awarded to Sir Eric Rideal, 856, 1018
DDT : Effects of, upon Different Species of Mosquitoes in Malaya (J. A. Reid), 863
Decay Scheme of Zinc-65 (S. E. Furberg), 1005
Decomposition : Ferric-ion Catalysed, of Hydrogen Peroxide and the Polymerization of Acrylonitrile (Dr. Adolf G. Parts), 79
Decomposition of Formic Acid by Periodate (Dr. P. B. Sarkar), 122
Decomposition of Sulphur Sesquioxide : Mode of (A. R. Vasudeva Murthy), 475
Deep-Sea Cores collected by the Swedish Deep-Sea Expedition 1947–48 : International Co-operation in the Analyses of the (C. D. Ovey), 148
Defects in Paints : Technology of, *review* by Dr. A. E. A. Werner, 715
Defence Research in the United States : Scientific Workers and, 857
Degradation of Deoxyribonucleic Acid by a 'Nitrogen Mustard' (Dr. J. A. V. Butler, L. Gilbert, D. W. F. James and W. C. J. Ross), 985
Democratic Planning : Freedom, Power and (Dr. Karl Mannheim), *review* by R. Brightman, 844
Democratic Planning and Liberty, *review* by R. Brightman, 844
Deoxycorticosterone : Estimation of, by a Modified Hagedorn–Jensen Procedure (Dr. J. J. Gordon and Janet E. Pelly), 603
Deoxynucleic Acid per Nucleus in the Liver and Kidney of Adult Rats : Relation between Polyploidy and the Amounts of (Marion F. Harrison), 248
Deoxypentose and Pentose Nucleic Acids : Separation of (Dr. Stephen Zamenhof and Prof. Erwin Chargaff), 604
Deoxypentosenucleoprotein (Rat Liver) : Composition of Histone prepared from (Robert Brunish, DeLorez Fairley and Prof. J. Murray Luck), 82
Deoxyribonuclease : Specific Requirements for the Action of (Dr. Christoph Tamm and Prof. Erwin Chargaff), 916
Deoxyribonucleic Acid : Degradation of, by a 'Nitrogen Mustard' (Dr. J. A. V. Butler, L. Gilbert, D. W. F. James and W. C. J. Ross), 985
Deoxyribosenucleic Acid Synthesis during Cell Division in Mouse Epidermis (Dr. W. S. Bullough and Dr. J. Pasteels), 608
Deoxyribosenucleoprotein Fibres : Effects of Ionizing Radiations upon Isolated (H. M. Rozendaal, W. D. Bellamy and T. H. Baldwin), 694
Deoxyribonucleosides on Paper Chromatograms : Detection of (Dr. J. G. Buchanan), 1091
Dephosphorylation of Adenosine Triphosphate in Muscular Contraction (W. F. H. M. Mommaerts and Joseph C. Rupp), 957
Depth Perception : Ocular Scanning and (J. Adamson), 345
Dermoid Cyst Fat (Ovarian) : Nature of (Dr. V. R. Wheatley), 1128
Deserts (Hot and Cold) : The Biology and Productivity of (Institute of Biology Conference on), 1068
Detection of Amino-Acids, Peptides, Proteins and other Buffering Substances on Paper : A New Method for (Dr. J. Porath and P. Flodin), 202
Detection of Aromatic Acids by Paper Partition Chromatography : Application of Buffered Solvent Systems to the (Mona E. Fewster and Dr. David A. Hall), 78
Detergents : Quaternary, and the Activity of Trypsin and Plasmin (Dr. Tage Astrup and Norma Alkjaersig), 565
Determination : An Accurate, of the Positions of Four Radio Stars (F. G. Smith), 555
  Theoretical, of Electron Density in Organic Molecules (Dr. O. Klement), 162 ; (Prof. C. A. Coulson, P. W. Higgs and N. H. March), 1039
Determination of Nucleic Acid Components by Paper Partition Chromatography : A Rapid Method for the (Jan-Erik Edström), 876
Determination of Sugars : A Colorimetric Method for the (M. Dubois, K. Giles, J. K. Hamilton, P. A. Rebers and Prof. F. Smith), 167
Deuterium Chloride containing an Impurity : Dielectric Properties of a Sample of (Dr. C. S. E. Phillips), 518
Deuterons : Scattering of 146-MeV. Protons by (J. M. Cassels, G. H. Stafford and Dr. T. G. Pickavance), 556
Development in British Colonial Territories : Research and, 691
Development in the Simon Engineering Group : Research and (Dr. W. Rhemallt Thomas), 284
Devonshire : The Scenery of, in relation to Weather and Climate (L. C. W. Bonacina), 1105
Di-atoms : Prediction of Internuclear Distances of (Dr. C. H. Douglas Clark), 911
Diabetes (Experimental) : Cocarboxylase in (Dr. D. Siliprandi and N. Siliprandi), 422
Diabetogenic Action of Growth-Hormone Preparations : Potentiation by Adrenocorticotrophin of the (Dr. E. Reid), 878
Diadema antillarum Philippi : Phenolases in the Echinoid (Prof. N. Millott and F. W. Jacobson), 878
2 : 4-Diamino Pyrimidine in the Treatment of Proguanil-resistant Laboratory Malarial Strains (I. M. Rollo), 332
Dielectric Absorption : Low-Frequency, and Direct-Current Conductivity in Quinol (J. S. Dryden and Dr. R. J. Meakins), 1121
Dielectric Behaviour of Human Blood at Microwave Frequencies (Dr. H. F. Cook), 247
Dielectric Crystals : Thermal Conductivity of—The 'Umklapp' Process (Dr. R. Berman, Prof. F. E. Simon and Dr. J. Wilks), 277
Dielectric Properties of a Sample of Deuterium Chloride containing an Impurity (Dr. C. S. E. Phillips), 518
Diene into Deeply Coloured Polyenes : Catalytic Conversion of a (B. Eisler and Dr. A. Wassermann, Dr. P. D. Farnsworth, D. Kendrick and Dr. R. Schnurmann), 459
Dietary Origin of Urinary Methyl-Histidine (S. P. Datta and H. Harris), 296
Differentiation of Skeletal Structures from Mouse Embryo Mince in the Peritoneum of Adult Mice (Theodore S. Hauschka), 1130
Diffraction Gratings (Optical Group of the Physical Society Symposium on), 67
Diffraction Investigations : Intense Gallium X-Rays for Microradiography and (A. Taylor), 471
Diffusion Respiration in Man (H. Enghoff, M. H. son Holmdahl and L. Risholm), 830
Digestion of Alpha-Cellulose by Larvæ of *Anobium punctatum* De Geer (D. Spiller), 209
Diluent : An Improved, for the Production of African Horse-sickness Virus Vaccine (A. Polson, J. Dent, S. M. Lawrence and P. J. van Rooy), 655
Dimethylpyruvic and α-Ketoglutaric Acids in Cultures of *Aspergillus niger* on various Substrates : Chromatographic Detection of Pyruvic, (Dr. T. K. Walker, A. N. Hall and J. W. Hopton), 1042
Dinitrophenyl Amino-Acids : Destruction of, by Tryptophane (Adrienne R. Thompson), 390
Dioscorea hispida, Dennst. : An Alkaloid of (A. R. Pinder), 1090
Diphtherial Culture Filtrate : Low Toxicity of the, and its relation to the Absence of Tyrosine in the Medium (Masahiko Yoneda), 879
Dipole Moments of Aliphatic and Aromatic Amines (Dr. E. G. Cowley), 705
Direct-Current Conductivity in Quinol : Low-Frequency Dielectric Absorption and (J. S. Dryden and Dr. R. J. Meakins), 1121
D.C. Positive Point-to-Plane Corona : Pre-Breakdown Discharges in (H. M. Gaunt and Dr. J. D. Craggs), 859
Disaccharide (Crystalline) : Isolation of a, Hyalobiuronic Acid, from Hyaluronic Acid (Maurice M. Rapport), Bernard Weissmann, Alfred Linker and Dr. Karl Meyer), 996
Discharge : Negative Point-to-Plane Corona—a New Mode of (Allan Greenwood), 41
Discharge Illuminant for Optical Systems capable of either Continuous or Flash Operation (E. J. G. Beeson and A. A. Webb), 1038
Discharge Physics : Some Aspects of (Physical Society Symposium on), 140
Discharges : Pre-Breakdown, in D.C. Positive Point-to-Plane Corona (H. M. Gaunt and Dr. J. D. Craggs), 859
Dische Diphenylamine Reaction : Application of the, to Pyrimidine Deoxynucleosides (Dr. T. G. Brady and E. McEvoy-Bowe), 299
Discontinuities in Supercooled Ionic Melts (Dr. N. N. Greenwood and R. L. Martin), 344
Discovery of the Expected Hæmagglutinin, Anti-Fy^b (Elizabeth W. Ikin, Dr. A. E. Mourant, H. J. Pettenkofer and G. Blumenthal), 1077
Diseases : Effect of, on the Serum Albumin of Animals (A. Polson), 421
Disinfectants and Disinfection : A Review of (Prof. H. Berry), 508
Display Purposes : Artificial Rock for (W. T. Stirling), 455
Dissociation of Complex Ions in Non-Aqueous Solvents (Dr. F. P. Dwyer and N. A. Gibson), 787
Distribution : Northward, of *Gammarus pulex* (L.) (D. M. Reid), 126
Distribution of Activity in a Source of Ionizing Radiation : A Method of making Visible the (Prof. W. V. Mayneord, R. C. Turner, S. P. Newbery and H. J. Hodt), 762
Documentation : World Conference on (Lucia Moholy), 1071
Dog : Cholinesterase Activity in the Secretions of the Pancreas of the, and Parotid of the Pig (Prof. R. A. McCance, L. M. Brown, Dr. R. S. Comline and D. A. Titchen), 788
Dogs : Cultivation of Canine Hepatitis Virus in Embryonated Hen's Eggs and its subsequent Transmission to (Dr. J. A. R. Miles, H. B. Parry, Dr. N. M. Larin and H. Platt), 699
Drosophila : Biology of (edited by M. Demerec), *review* by H. Oldroyd, 803
Drosophila melanogaster : Antennæ and Mating Behaviour in (Dr. Michael Begg and Elsie M. Packman), 953
Drugs : Natural and Synthetic, *review* by Prof. J. W. Cook, 438
Dry Oxidation and Wet Corrosion (Dr. U. R. Evans), 853
Drying : Freezing and (Institute of Biology Symposium on), 851

- Duddell Medal for 1951 of the Physical Society awarded to Dr. A. B. Wood, 588
- Dutch-type White-spotting in Rabbits (Roy Robinson), 300
- Dwarf People : Mythical, in Polynesian Legend, 639
- Dyes : Modification of Crystal Habit of Inorganic Salts with (Dr. J. Whetstone), 663
- Dynamics : Advanced (E. Howard Smart), Vols. 1 and 2, *review* by Prof. T. G. Cowling, 714
- Dynamics for Mathematicians, *review* by Prof. T. G. Cowling, 714

- EARTH : Chemistry of the, *review* by Prof. K. C. Dunham, 843
  - Crustal Layers of the (Prof. A. L. Hales), 163 ; (P. L. Willmore), 164
- Earthquake Activity in New Zealand during 1949, 1067
- Earthquake Azimuths : Determination of, from Observations at a Single Station, 1106
- East : The Middle; a Physical, Social and Regional Geography (Dr. W. B. Fisher), *review* by R. N. R. B., 928
- Echinoid, *Diadema antillarum* Philippi : Phenolases in the (Prof. N. Millott and F. W. Jacobson), 878
- Econometrics : Studies in, *review*, 620
- Economic Models (Dynamic) : Statistical Inference in (edited by Tjalling C. Koopmans), *review*, 620
- Ecotypes of Dioecious *Melandrium dioicum* (L. emend.) Coss. & Germ. : Cytology of the (Dr. H. G. Baker and W. Jackson), 747
- Education : Biology in, 257
  - Evolution and (Conference on), 899
  - Further, in the Welfare State, 923
  - Higher, in British Colonial Territories, 591
  - Higher Technological, in Great Britain, 543
  - Higher Technological, in Great Britain (British Association, Section L (Education), Discussion on), 458
  - Medical, in Turkey (Prof. F. Nafiz Uzluk), 821
  - Mid-Century—Retrospect and Prospect in (Sir Hector Hetherington), 232
  - Technical and Technological, in Great Britain, 709
  - University, and Subsequent Careers, 18
- Education (Adult) : English Universities and (S. G. Raybould), 886, 923
- Education (American) : Importance of Science in (Ernst A. Hauser), 866
- Education (Further) : Provision of, 885
- Education in the Colonies, 393
- Education in the University of Edinburgh, 812
- Education for Marriage, *review* by Dr. Eliot Slater, 1035
- Education and Industrial Efficiency, 129
- Education and Leadership (Dr. Eric James), 754
- Education and Technology : Leadership, 753
- Education and Training : Engineering, 14
- Eelworms (Nematodes) as Pests of Mushrooms (Charles A. Thomas and George H. Mitchell), 274
- Effigy of Robert Boyle, 638
- Egg Coloration of the Parasite *Bracon gelechiae* Ashmead (Braconidae) : Effect of Hosts on the (G. C. Sen Gupta), 793
- Egg-Shell Formation in Trematodes and Cestodes as demonstrated by the Methyl or Malachite Green Techniques (Dr. J. D. Smyth), 322
- Eggs (Birds') : Palatability of (Dr. Hugh Cott), 1110
- Egypt : Flora of (Vivi Täckholm and Mohammed Drar), Vol. 2, *review* by W. A. S., 486
- Egypt (Ancient) : A Royal Head from (Dr. George Steindorff), 499
- Eighteenth Century Lectureship in Chemistry (edited by Dr. Andrew Kent), *review* by L. F. Gilbert, 969
- Elastic Constants of Alkali Halide Crystals (Sir K. S. Krishnan and Dr. S. K. Roy), 869, 983
- Elastic Constants of Galena (Prof. S. Bhagavantam and T. Seshagiri Rao), 42
- Elastin from Human Tissue and from Ox Ligament (Dr. David A. Hall), 513
- Electric Eyes (A. J. Fawcett), 499
- Electric Shock and the Regeneration of the Corneal Epithelium of Rabbits (Margarete Holzbauer and Prof. R. Rigler), 919
- Electrical Activity of the Nervous System (Dr. Mary A. B. Brazier), *review*, 972
- Electrical Conductivity during Bacterial Growth : Changes in (Prof. K. Krishnamurti and S. R. Kate), 170
- Electrical Conductivity and Magnetic Susceptibility of Ovalene (Prof. Hideo Akamatu, Hiroo Inokuchi and Takashi Handa), 520
- Electrical Development : Montefiore Prizes for, 413
- Electrical Discharge : Physics of (Prof. F. Llewellyn Jones), 140
- Electrical Systems : Nonlinear Vibrations in Mechanical and (J. J. Stoker), *review* by Prof. H. T. H. Piaggio, 49
- Electrical Transients · Transformation Calculus and (Prof. Stanford Goldman), *review*, 577
- Electricity : A History of the Theories of Aether and (Sir Edmund Whittaker), revised edition, *review* by Prof. W. H. McCrea, 1053
- Electricity and Magnetism, Classical and Modern (Dr. G. B. Deodhar and K. S. Singwi), *review* by A. H., 717
- Electrification (Static) : Reduction of, by means of Inhibiting Compounds (G. W. Graham), 871
- Electrode Unit : A Convenient 'Hanging-drop' Glass (Dr. Charles S. Hanes), 566
- Electrodecanter for Hydrophobic Colloids : A Fast Continuous Electrodialyser for Hydrophilic Colloids, and a Fast Continuous (Prof. A. J. Rutgers and R. Swyngedouw), 727
- Electrodialyser for Hydrophilic Colloids : A Fast Continuous, and a Fast Continuous Electrodecanter for Hydrophobic Colloids (Prof. A. J. Rutgers and R. Swyngedouw), 727
- Electrodynamics : Superconductive, *review* by Dr. K. Mendelssohn, 670
- Electrolytes : Absorption of Sound in Aqueous Solutions of (K. Tamm and G. Kurtze), 346
- Electrolytic Tank : Solution of Polynomial Equations with the aid of the (L. Tasny-Tschiassny and A. G. Doe), 702
- Electromagnetic Means : Separation of Stable Isotopes by (W. D. Allen), 451
- Electromagnetic Theory (Oliver Heaviside), *review* by Prof. Willis Jackson, 136 ; erratum, 236
- Elektromagnetische Schirmung in der Fern- und Hochfrequenztechnik (Dr. Heinrich Kaden), *review* by R. E. Burgess, 717
- Electromagnetism : The Principles of (Dr. E. B. Moullin), second edition, *review* by Prof. James Greig, 4
- Electromagnetism for Engineers, *review* by Prof. James Greig, 4
- Electron Beams (Low-Energy) : Standing-Waves in (Dr. W. W. H. Clarke and Dr. L. Jacob), 1120
- Electron Concentration in Flames : A Cavity Resonator Method for (Dr. T. M. Sugden and B. A. Thrush), 703
- Electron Density in Organic Molecules : Theoretical Determination of (Dr. O. Klement), 162 ; (Prof. C. A. Coulson, P. W. Higgs and N. H. March), 1039
- Electron Density in the Solar Corona : A New Radio Method for Measuring the (K. E. Machin and F. G. Smith), 599
- Electron Diffraction by Clay Minerals with a Fibrous or Rod-like Habit (D. R. Knapp and Dr. R. P. Mitra), 380
- Electron Microscope : Elementary Electron Optics and Factors affecting the (Electron Microscope Society of America Symposium on), 369
  - Metallurgical Applications of the (Institute of Metals, in association with the Chemical Society, the Faraday Society, the Institute of Physics, the Institution of Electrical Engineers, the Iron and Steel Institute, the Physical Society, and the Royal Microscopical Society Symposium on), *review* by F. C. T., 179
  - Observations of the Golgi Substance with the (Dr. A. J. Dalton), 244
  - Structure of Sannhemp (*Crotalaria juncea* Linn.) Mosaic Virus with the (Dr. N. N. Das Gupta, M. L. De and S. P. Raychaudhuri), 114
- Electron Microscope in Metallurgy, *review* by F. C. T., 179
- Electron Microscope Study of Nucleic Acid (S. T. Bayley), 470
- Electron-Microscopic Observations on the Xylem Elements of a Fossil Plant (A. Wesley and B. Kuyper), 137
- Electron Microscopy : Bibliography of (edited by Dr. V. E. Cosslett), *review* by L. V. Chilton, 928
  - Technique of (Electron Microscopy Group of the Institute of Physics Conference on), 819
- Electron Microscopy at High Resolution : A Method for making Ultra-Thin Tissue Sections for (Fritiof Sjöstrand), 646
- Electron Microscopy of Chick Embryo Membrane infected with *PR-8* Influenza (Dr. Ralph W. G. Wyckoff), 651
- Electron Microscopy of β-Lactoglobulin Crystals : Crystal Structure of a Low Molecular Weight Protein—(Dr. I. M. Dawson), 241
- Electron Optics : Introduction to (Dr. V. E. Cosslett), second edition, *review*, 803
- Electron Optics and Factors : Elementary, affecting the Electron Microscope (Electron Microscope Society of America Symposium on), 369
- Electronic Devices, *review* by Dr. U. W. Arndt, 50
- Electronic Theories of Organic Chemistry, *review* by Dr. J. W. Baker, 92
- Electronics (P. Parker), *review* by Dr. U. W. Arndt, 716
  - Applied (C. A. Taylor), 283
- Electronics in Nuclear Science and Engineering (Dr. Denis Taylor), 948
- Electrons (Polarized) : Detection of Circularly Polarized γ-Rays and the Production of (Prof. Otto Halpern), 782
- Electrons in Spark Gaps : Cold Emission of (Prof. F. Llewellyn Jones and Dr. E. T. de la Perrelle), 160
- Electrophoresis Apparatus for Analysing several Sera Simultaneously (Dr. A. Polson), 996
- Electro-physiological Work : Micro-electrode for (J. Worst), 749
- Electroretinography : Cone, by Flicker (Dr. E. Dodt), 738
- Electrostatic Interaction and Intramolecular Configuration : A Novel Connexion between (Dr. G. Baddeley, Dr. G. Holt, Dr. N. H. P. Smith and F. A. Whittaker), 386
- *Elliott Journal*, No. 1, 62
- Embryology : Genetics and (British Association, Section D (Zoology), Discussion on), 415
- Embryonic Development in the Seed Plants, *review* by Prof. R. C. McLean, 619
- Emission from Neon–Oxygen Mixtures : Atmospheric Oxygen Bands in, and in Night Sky and Auroral Luminescences (G. Kvifte), 741
- Employment (Full) : Labour Turnover under (Dr. Joyce R. Long), 993
  - Absence under (Hilde Behrend), 993
- *Endeavour* Prizes at the British Association, 274
- Engineer : The Education and Training of the (Institution of Civil Engineers Discussion on), 14
- Engineering : A Century of Developments in (E. K. Frankl), 237
  - Coastal (Southwest Research Institute, San Antonio, Texas, in co-operation with the University of California, Texas A. and M. Research Foundation, Rice Institute, University of Houston, and the Houston Branch of the American Society of Civil Engineers, second Conference on), 456
  - Electronics in Nuclear Science and (Dr. Denis Taylor), 948
  - 2,000 Years of (Sir Claude Gibb), 229
- Engineering Education and Training, 14
- Engineering Technology : Research Discussions on (Departments of Civil and Mechanical Engineering of the University of Nottingham), 455
- Engineers : Electromagnetism for, *review* by Prof. James Greig, 4
- England (North of) : Television in the, 680
- England and Wales : 1951 Population Census of (E. Grebenik), 580
- English Channel : Influences of Tidal Streams on Oceanographic and Climatic Conditions in the Sea as exemplified by the (Dr. G. Dietrich), 8
- English Farming : The Story of, *review* by Sir John Russell, 307
- English Husbandry from the Earliest Times to the Present Day (Robert Trow-Smith), *review* by Sir John Russell, 307
- English Universities and Adult Education (S. G. Raybould), 886, 923
- Ensilage : Handbook of, *review* by Prof. H. G. Sanders, 620
- Entomological Testing Methods, 275
- Entomology (Applied) : Insect Physiology and, 974
- Environmental Conditions (Extreme) : Life and Work in (British Association, Section A (Mathematics and Physics), Discussion on), 363
- Enzymatic Conversion of the Stereoisomers of *iso*Leucine to the Corresponding α-Keto-Acids (Dr. Alton Meister), 1119
- *Q*-Enzyme : Carbohydrate Primers for (S. A. Barker, A. Bebbington and Dr. E. J. Bourne), 834
- Enzyme from Lactic Streptococci : 'Streptozyme', a Lytic (Dr. A. Hirsch and Dorothy M. Wheater), 607
- Enzyme Preparations : Bacterial, oxidizing Inositol and their Inhibition by Colchicine (Robert E. Franzl and Prof. Erwin Chargaff), 955

Enzymes : Detection of, by the Agar-Plate Method and its Application to Paper Chromatography (W. W. Reid), 739
  Separation of, by Paper Chromatography (Prof. K. V. Giri and A. L. N Prasad), 786
Enzymes (Gustatory and Olfactory) : Localization of, in the Rabbit, and Problems of Taste and Smell (A. F. Baradi and Dr. G. H. Bourne), 977
Eosinophil Cell as seen in the Llama (Dr. F. Duran-Jorda), 1129
Eosinophil Count : Adrenotropic Hormone (ACTH), Aminopterin and (Dr. Vincenzo Traina), 250
Epitaxis of Rubidium Iodide on a Barium Stearate Substrate deposited on Mica (A. A. Fuller), 471, 899
Epithelium of the Small Intestine : Histological Changes in the, during Protein Absorption in the New-born Animal (Dr. R. S. Comline, H. E. Roberts and D. A. Titchen), 84
Equipment to Estimate Radiocarbon : Simple (O. Feldstein and Dr. E. Broda), 599
Ergine : Crystal Structure of (J. L. DeVries and Prof. R. Pepinsky), 431
Ergothioneine in the Seminal Vesicle Secretion (Dr. E. Leone and Dr. T. Mann), 205
Erythrocruorin : Relationship between Hæmoglobin and (Prof. D. Keilin and Dr. E. F. Hartree), 266
Erythrocyte Antibodies as a Cause of Abortion in Cattle (J. Laing and F. Blakemore), 656
Escherichia coli : Ribosidation of 4-Aminoimidazole-5-carboxamide by (R. Ben-Ishai, Dr. Ernst D. Bergmann and B. E. Volcani), 1124
  Utilization of Gluconate and Glucose in Growing and Virus-Infected (Seymour S. Cohen), 746
Escherichia coli Mutant (Serineless) : Enhancement of the Normal Reversion-rate of a, by certain Organic Acids (Dr. Barbara E. Wright), 1087
Ethical Problems of the Scientific Worker (Cambridge Branch of the Association of Scientific Workers Conference on), 1112
Ethyl Alcohol : Protective Action of, on Irradiated Mice (Edith Paterson and Joyce J. Matthews), 1126
Ethylene : Observation of Cool Flames with (J. R. Abbott and S. A. Miller), 474
Ethylenediamine D-Tartrate in Water : Solubility of (L. A. Dauncey and J. E. Still), 34
Europe (North) : Archæological Dating of the Climatic Change in, about A.D. 1300 (Dr. Axel Steensberg), 672
European Breeds of Cattle exposed to High Environmental Temperatures : Heat Tolerance of (J. Dobinson), 882
European Larch in Great Britain : General Volume Tables for (F. C. Hummel, T. W. Irvine and J. Jeffers), 111
Evolution : Non-adaptive Characters in (Dr. G. S. Carter), 700
  Non-adaptive or Neutral Characters in (Dr. A. J. Cain), 1049 ; (Dr. G. S. Carter), 1049
  So-called Non-adaptive or Neutral Characters in (Dr. A. J. Cain), 424
  Vertebrate Palæontology and (British Association, Sections C (Geology) and D (Zoology), Discussion on), 583
Evolution and Education : Conference on, 899
Evolutionary Theory, *review* by Prof. Sewall Wright, 351
Ewe : Inhibitory Action of Artificial Light on the Sexual Season of the (Dr. E. S. E. Hafez), 336
Ewe (Pregnant) : Prevention of Swayback Symptoms in Lambs by administration of Copper Sulphate to the (Dr. George Dunlop), 728
Ewe Lambs : Sexual Season in (Dr. E. S. E. Hafez), 1046
Ewe's Colostrum : Absorption of Anti-Nematode Antibodies from, by the New-born Lamb (Daisy B. Filmer and T. J. McClure), 170
Excretion (Vertebrate) : Survey of Existing Knowledge of Biogeochemistry, 3, The Biogeochemistry of (George Evelyn Hutchinson), *review* by Sir James Scott Watson, 925
Exhalation of Carbon Dioxide by the Mouse : Effect of Irradiation by X-Rays on the (Prof. G. Hevesy and A. Forssberg), 692
Explosions of Stars : Hydrogen Exhaustion and (Dr. G. Gamow), 72
Extinction Coefficient and the Particle Size : Relationship between the (Dr. Horace E. Rose), 784
Extra-Adrenal Action of Adrenotropic Hormone (Prof. Hans Selye), 149
Eye : Changes in Colour Sensitivity of the, with Posture (Dr. J. N. Aldington), 86 ; (A. Blackie), 524 ; (F. Taylor), 524
Eyes : Electric (A. J. Fawcett), 499

FACTOR in Soil-extract Responsible for Bacterial Growth-stimulation : Nature of the (Dr. C. B. Taylor), 115
Factor *Rb* Activity in Human Plasma (Dr. Ellsworth C. Dougherty), 880
Fallopian Tubes : Fertilizing Capacity of Spermatozoa deposited into the (Dr. M. C. Chang), 697
Farben (I. G.) Central Laboratory Index (Technical Information and Documents Unit of the Department of Scientific and Industrial Research microfilm of the), 274
Farey Series of Order 1025, displaying Solutions of the Diophantine Equation $bx-ay=1$ (designed and compiled by Prof. E. H. Neville), *review* by Dr. R. A. Rankin, 177
Farm Animals in India : The Feeding of (Dr. P. E. Lander), *review* by Dr. John Hammond, 440
Farm Practice (Modern) : A Pioneer in, 145
Farm Products : Storage of (British Association, Section M (Agriculture), Discussion on), 488
Farming : Impact of Science on, *review*, 670
  Neo-Vitalism and, *review* by Sir John Russell, 926
  The New (Dr. D. H. Robinson), new edition, *review*, 670
Farming (English) : The Story of, *review* by Sir John Russell, 307
Farming (Marginal Land) : Problems of (British Association, Sections F (Economics) and M (Agriculture), Discussion on), 457
Farming and the Future : Food, (Friend Sykes), *review* by Sir John Russell, 926
Fast-Neutron Dosimetry : Use of Nuclear Research Emulsions for (Dr. H. A. B. Simons), 835
Faster than Thought—The Ferranti Nimrod Digital Computer (Ferranti, Ltd.), 70
Fat (Ovarian Dermoid Cyst) : Nature of (Dr. V. R. Wheatley), 1128
Fat Synthesis : Stimulation by Insulin of *in vitro*, by Mammary Tissue studied with Carbon-14 and Tritium (Judith H. Balmain, Dr. S. J. Folley and Dr. R. F. Glascock), 1083
Fat and Muscle (Human) : Thermal Conductivity of (Dr H. Stafford Hatfield and Dr. L. G. C. Pugh), 918
Fats : Methods of Analysis of Oils and (British Standard 684 : 1950), 103
Fatty-acid Mixtures (Binary) : Solidification Curves and Crystal Spacings of (M. Fieldes and L. Hartman), 74
Fauna (Bottom) : The Philippine Trench and its (Dr. Anton Fr. Bruun), 692
Fauna of Great Britain : The Littoral (Dr. N. B. Eales), second edition, *review* by Dr. D. P. Wilson, 51
Fawley Refinery (H. B. Milner), 541
Fear and Social Structure (Dr. Grantly Dick Read), 413
Feather Barbs : Surface Cells of (L. Auber and H. M. Appleyard), 736
Feeding Relationships of the Fishes of Singapore Straits : The Food and (Tham Ah Kow), 640
Fellowship : Knoop Research, in Economics of the University of Sheffield awarded to D. C. Corner, 726
  John Stokes Research, of the University of Sheffield awarded to H. L. Kornberg, 726
Fellowships : Dorothy Temple Cross Research Travelling, in Tuberculosis (Medical Research Council Awards), 189
  Leverhulme Research, 19
  Ramsay Memorial, for Chemical Research, 983
  Research (National Institute of Sciences of India), 498
  Rockefeller Travelling, in Medicine (Medical Research Council Awards), 189
  Salters', for 1951–52, 641
  Textile Research (Commonwealth Scientific and Industrial Research Organization), 683
Fellowships for Study in the United States (Commonwealth Fund of New York), 683
Female Elements in Fertilization : Activation and the Correlation between Male and (C. R. Austin), 558
Fermentation of Malt Extract (Mary P English), 391
Fermentation-inhibiting Properties of Orange Oil (D. A. A. Mossel), 999
Fern- und Hochfrequenztechnik : Die elektromagnetische Schirmung in der (Dr. Heinrich Kaden), *review* by R. E. Burgess, 717
Fernbeben aus Oberflächenwellen : Über die Bestimmung des Azimuts von (Prof. W. Hiller), 1106
Ferranti Nimrod Digital Computer : Faster than Thought—the (Ferranti, Ltd.), 70
Ferric-ion Catalysed Decomposition of Hydrogen Peroxide and the Polymerization of Acrylonitrile (Dr. Adolf G. Parts), 79
Ferrite : Temperature Dependency of Half Line-Width in (Prof. Toshihiko Okamura and Yoshiharu Torizuka), 872
Ferromagnetic Material : Effect of a Magnetic Field on the Propagation of Sound Waves in a (J de Klerk), 963
Ferromagnetic Resonance Absorption and a New Transition in $NiOFe_2O_3$ at Low Temperature (Prof. Toshihiko Okamura), 162
Ferrous Oxide : Reduction of (O. H. Gellner and Dr. F. D. Richardson), 23
Ferrous Sulphide : Thermodynamics of (C. B. Alcock and Dr. F. D. Richardson), 661
Fertility (Society for the Study of Fertility Conference on), 286
Fertility of Mammals : Factors Concerned in, 286
Fertilization : Activation and the Correlation between Male and Female Elements in (C. R. Austin), 558
Fertilizing Capacity of Spermatozoa deposited into the Fallopian Tubes (Dr. M. C. Chang), 697
Fibres : Submicroscopic Structure of, and their Formation (Dr. Edgar Ribi), 1082
Field Stations : Zoology at the Marine, Freshwater and (British Association, Section D (Zoology), Discussion on), 546
Field Theory (Non-symmetric) : The Point-Charge in the (A. Papapetrou and Prof. E. Schrodinger), 40
Field-Work in Zoology, 546
Fighting ? : Could an Arms-Race End without (Dr. L. F. Richardson), 567, 920 ; (M. R. Horne), 920
Fijian Hæmatozoa : A Contribution to the Study of (Dr. M. Laird), 640
Filariasis in the Pacific (Sir Philip Manson-Bahr), 776
Film Research : Instructional, in Pennsylvania (C. Denis Pegge), 775
Films (Evaporated) : Contamination of, by the Supporting Material of the Source (O. S. Heavens), 664
Films and Surfaces : The Rheology of (British Society of Rheology and the Local Section of the Chemical Society Conference on, at University College, Exeter), 369, 945
Filter Paper : Movement of Proteins on (Dr. D. A. Hall and Dr. F. Wewalka), 685; (Dr. A. E. Franklin, Prof. J. H. Quastel and Dr. S. F. Van Straten), 687
Filter System : A Simplified Coupled, for Adsorption Chromatography (Dr. David A. Hall), 124
Finger Nails : Occurrence of Thin Membranes in the Surface Layers of Human Skin and in (Gosta Lagermalm, Bo Philip and Joel Lindberg), 1080
Fish Collections from the Leeward and Line Islands, 1027
Fisheries : Australian (edited by I. G. Macinnes), *review* by C. F. H., 973
Fisheries Researches in Singapore Straits, 640
Fishes as Pets : Tropical (Christopher W. Coates), reprint, *review*, 928
Fishes of Singapore Straits : The Food and Feeding Relationships of the (Tham Ah Kow), 640
Flagella : Bacterial (Prof. Adrianus Pijper), 749 ; (Dr. Claes Weibull), 750
Flames : A Cavity Resonator Method for Electron Concentration in (Dr. T. M. Sugden and B. A. Thrush), 703
  Polyhedral Diffusion (Dr. J. E. Garside and B. Jackson), 1085
Flames (Cool) : Observation of, with Ethylene (J. R. Abbott and S. A. Miller), 474
Flames burning with Oxides of Nitrogen : Spectra of (B. B. Fogarty and H. G. Wolfhard), 1122
Flamingo City (G. K. Yeates), *review* by Seton Gordon, 621
Flax Fibre Polyuronide Hemicellulose : Paper Chromatography of (G. C. Whiting), 833
Flicker : Cone Electroretinography by (Dr. E. Dodt), 738
Flora : The West Australian (Sir Edward Salisbury), 57
Flora (British) : Recent Research and Additions to the (J. E. Lousley), 934
Flora of Egypt (Vivi Täckholm and Mohammed Drar), Vol. 2, *review* by W. A. S., 486

- Flora of the Land of Israel (Naomi Feinbrun and Michael Zohary), *review* by E. J. S., 51
- Flowering : Vegetative Propagation from the Broccoli Curd after Suppression of (K. E. Haine), 919
- Flowers and Shrubs : Pests of (G. Fox Wilson), second edition, 321
- Fluids : Ultrasonics in (Dr. E. G. Richardson), 106
- Fluorescence : Determination of Sodium Gentisate by Chromatography and (Dr. L. Nanninga and B. Bink), 389
- Fluorescent Substances : Photo-inactivation of the Plant Hormone Indoleacetic Acid by (Dr. Mario G. Ferri), 334
- Fluorescent Substances in the Neutral Fraction of Urinary Extracts : Determination and Occurrence of (Prof. Bernhard Zondek and Michael Finkelstein), 831
- Fluorine Chemistry (edited by Dr. J. H. Simons), Vol. 1, *review* by Dr. H. A. Skinner, 621
- Fluorine Chemistry (Organic) : Recent Advances in (Dr. R. N. Haszeldine), 1028
- Fluorine Gas compressed into Steel Cylinders (Imperial Smelting Corporation, Ltd.), 236
- Fluorochromy as an Aid in the Resolution of the Specific Granules of the Islets of Langerhans (Dr. W. Stanley Hartroft), 1000
- Fluorogenic Compounds : Fluorometric Determination of Natural Œstrogens in Urine—Elimination of (Michael Finkelstein), 830
- Fluorometric Determination of Natural Œstrogens in Urine—Elimination of Fluorogenic Compounds (Michael Finkelstein), 830
- Fly Reactions to Insecticidal Deposits—a New Test Technique (Dr. F. Baranyovits), 960
- Fonctions : Leçons sur la théorie des (Émile Borel), quatrième édition, *review*, 758
- Food : Chemicals in (Dr. Francis Aylward), 778
  - Problems arising from the use of Chemicals in (Food, Agriculture and Fine Chemicals Groups of the Society of Chemical Industry Conference on), 236
  - Unicellular Algæ as a Source of (Dr. M. J. Geoghegan), 426
- Food, Farming and the Future (Friend Sykes), *review* by Sir John Russell, 926
- Food and Feeding Relationships of the Fishes of Singapore Straits (Tham Ah Kow), 640
- Forage and Pasture Crops (W. A. Wheeler), *review* by J. O. Green, 575
- Foreman : The, a Study of Supervision in British Industry (National Institute of Industrial Psychology), *review* by T. H. Hawkins, 671
- Foremanship : The New, *review* by T. H. Hawkins, 671
- Foremanship Training in Technical Colleges (British Institute of Management Report on), 367
- Forest Policy in Uganda (Prof. E. P. Stebbing), 507
- Forest Research in Sweden, 777
- Forestry : Animals and (British Association, Sections D (Zoology) and K* (Forestry), Symposium on), 449
- Forestry in British Guiana, 640
- Forestry in Trinidad and Tobago, 1026
- Forestry in the University of Edinburgh, 812
- Forestry and Conservation in South Africa, 726
- Forests : American Deciduous, *review* by Sir Edward Salisbury, 309
- Forests of Eastern North America : Deciduous (Prof. E. Lucy Braun), *review* by Sir Edward Salisbury, 309
- Form : Aspects of (edited by Lancelot Law Whyte), *review* by F. I. G. Rawlins, 574
- Formic Acid : Decomposition of, by Periodate (Dr. P. B. Sarkar), 122
- Fossil Plant : Electron-Microscopic Observations on the Xylem Elements of a (A. Wesley and B. Kuyper), 137
- Fourier Methods (Prof. Philip Franklin), *review*, 848
- Fourier Synthesis by Optical Interference (A. W. Hanson, C. A. Taylor and Dr. H. Lipson), 160
- Franklin Medal of the Franklin Institute, Philadelphia, awarded to Sir James Chadwick, 683
- Freedom, Power and Democratic Planning (Dr. Karl Mannheim), *review* by R. Brightman, 844
- Freedom of Speech and Thought, 305
- Freeze-Drying : Preservation of Biological Materials by (Dr. R. J. C. Harris), 851
- Freezing and Drying (Institute of Biology Symposium on), 851
- *French Bibliographical Digest*, No. 6, Bibliography of French Mathematics and Astronomy during 1940–48, 188
- French Mathematics and Astronomy during 1940–48 : Bibliography of, 188
- French Palæontological Documentation and Translation Service, 857
- Freshwater Amphipoda (British) : Distribution of (G. Fryer), 435
- Freshwater Nematodes : Soil and (Dr. T. Goodey), *review* by Prof. C. H. O'Donoghue, 801
- Freshwater Phytoplankton, *review* by Prof. F. E. Fritsch, 396
- Freshwater and Field Stations : Zoology at the Marine, (British Association, Section D (Zoology), Discussion on), 546
- Fringes (Multiple-Beam Interference) : Superposition Effects in (Audrey M. Glauert), 861
- Fuel and Power Resources (Appointment by the Minister of Fuel and Power of a Committee to consider the use of), 274
- Function Theory, *review*, 758
- Functional Operators (John von Neumann), Vol. 1, *review*, 717
- Functions : Theory of, *review* by Prof. H. T. H. Piaggio, 216
- Fungi : Formation of Extra-cellular Nitrogen Compounds by (A. G. Morton), 333
- Fungi (Higher) : Effect of certain Nucleic Acid Constituents on the Growth of some (Dr. Nils Fries), 1045
- Fungi (Pathogenic) : *In vitro* Fungistatic Action of Phenanthrolines against (Dr. F. Blank), 516
- Fungi growing on Agar : Permanent Preparations of (Dr. C. L. Duddington and Sylvia M. Dixon), 38
- Fungistatic Action of Phenanthrolines against Pathogenic Fungi : *In vitro* (Dr. F. Blank), 516
- Funktionentheorie (Prof. Constantin Carathéodory), *review* by Prof. H. T. H. Piaggio, 216
- *Fusaria* isolated from South Indian Soils (Dr. C. V. Subramanian), 561

- GALACTIC Radio Spectrum : Observation of a Line in the—Radiation from Galactic Hydrogen at 1,420 Mc./sec. (H. I. Ewen and Prof. E. M. Purcell), 356 ; (Dr. J. L. Pawsey), 358 ; The Interstellar Hydrogen Line at 1,420 Mc./sec., and an Estimate of Galactic Rotation (C. A. Muller and Prof. J. H. Oort), 357
- Galena : Elastic Constants of (Prof. S. Bhagavantam and T. Seshagiri Rao), 42
- Galled and Virus-infected Leaves : Benefits to Aphids from Feeding on (Dr J. S. Kennedy), 825
- Gallium, Germanium and Arsenic : Mechanical Properties of α-Solid Solutions of Copper, with Zinc, (Dr. N. P. Allen, T. H. Schofield and A. E. L. Tate), 378
- Gallium and Indium Monofluorides : Ultra-Violet Absorption Spectra of (D. Welti and R. F. Barrow), 161
- Gallium X-Rays : Intense, for Microradiography and Diffraction Investigations (A. Taylor), 471
- γ-Radiation from Oriented Cobalt-60 Nuclei : An Experiment on Nuclear Alignment—the Anisotropy of (J. M. Daniels, Dr. M. A. Grace and F. N. H. Robinson), 780
- γ-Rays (Circularly Polarized) : Detection of, and the Protection of Polarized Electrons (Prof. Otto Halpern), 782
- *Gammarus pulex* (L.) : Northward Distribution of (D. M. Reid), 126
- Garden Handbook : The Complete (Maron J. Simon, John Elliott, Dickson W. Pierce and Beatrice P. Hendrix), *review* by J. S. L. Gilmour, 52
- Gas Effects : Inert, in the Oxidation of Hexane (N. J. H. Small and Prof. A. R. Ubbelohde), 201
- Gases : A Highly Sensitive Phase-Contrast Refractometer for Liquids and (Erik Ingelstam), 960
  - A New Method for Measuring the Atomic Heats of (Prof. H. S. Gregory and L. I. Sherif), 1123
- Gaster (Leon) Memorial Premium for 1951 of the Illuminating Engineering Society awarded to H. W. Cumming, 641
- Geiger Counter : Estimation of Radioactive Hydrogen as Tritiobutane in the (Dr. R. F. Glascock), 121
  - A Toroidal (C. P. Haigh), 246
- Geiger–Müller Liquid Counters : Calibration of, by the Radioactivity o Potassium-40 (Dr. T. A Chalmers), 870
- Gel-type Gelatine Films : Mechanical Properties and Structure of Sol-type and (E. Bradbury and C. Martin), 837
- Gelatin (Synthetic Polypeptides and) : Optical Rotation and Chain Folding in (Dr. Conmar Robinson and M. J. Bott), 325
- Gelatine Films (Sol-type and Gel-type) : Mechanical Properties and Structure of (E. Bradbury and C. Martin), 837
- Gelatinous Mass in Rabbit Semen (Dr. D. P. Mukherjee, M. P. Johari and P. Bhattacharya), 422
- Gene Function in the Homologous and Heterologous Induction of α-Glucosidases in Yeast by α-Glucosides (Prof. Shlomo Hestrin and Prof. Carl C. Lindegren), 913
- Genes and Mutations (Cold Spring Harbor Symposium on), 732
- Genetics . Elementary (Wilma George), *review* by Dr. G. Pontecorvo, 887
- Genetics at Adelaide, 234
- Genetics and Anthropology, *review* by Dr. J. S. Weiner, 1054
- Genetics and Embryology (British Association, Section D (Zoology), Discussion on), 413
- Genetics and the Races of Man (Prof. William C. Boyd), *review* by Dr. J. C. Weiner, 1054
- Geochemistry (Dr Kalervo Rankama and Prof. Th. G. Sahama), *review* by Prof. K. C. Dunham, 843
- Geography : The Centenary of Section E of the British Association for the Advancement of Science (Dr. O. J. R. Howarth), 227
- Geography in the Service of Mankind (E. O. Gifford), 314
- Geology : Australian—a Regional Synthesis, *review* by Prof. C. E. Tilley, 131
- Geology of the Commonwealth o' Australia (the late Sir T. W. Edgeworth David), review by Prof. C. E. Tilley, 131
- Geology and Military Strategy (Prof. W. B. R King), 226
- Geology and Mineral Resources in the British Colonies (Prof. R. C. Dunham), 1109
- Geomagnetic Field : Remanent Magnetism of Rocks and the History of the (J. Hospers), 1111
- Géométrie algébrique : L'Analysis situs et la (S. Lefschetz), *review*, 717
- Germanium Tetrafluoride : Raman and Infra-Red Spectra of (A. D. Caunt, L. N. Short and Dr. L. A. Woodward), 557
- Germanium and Arsenic: Mechanical Properties of α-Solid Solutions of Copper, with Zinc, Gallium, (Dr. N. P. Allen, T. H. Schofield and A. E. L. Tate), 378
- Germany during the Period 1939–1945 : The Acetylene Industry and Acetylene Chemistry in (Dr. R. Owens and Dr. A. W. Johnson), 939
- Germany (West) : American Scientific Mission to, 320
- Germination of Watercress Seeds : Effect of Light on the (H. W. Howard and A. G. Lyon), 253
- Germination of Zygotes of *Chlamydomonas* : Effect of *cis*-Cinnamic Acid and some Isomeric Compounds on the (Prof. Franz Moewus and Basudev Banerjee), 561
- Glasgow Chemists, *review* by L. F. Gilbert, 969
- Glass : Preservation of, from Corrosion (Max Unwin), 235
- Glasshouse : Science and the (William J. C. Lawrence), second edition, *review* by Wilfred Corbett, 397
- Glasshouse Crops : Production of, *review* by Wilfred Corbett, 397
- Gluconate and Glucose : Utilization of, in Growing and Virus-infected *Escherichia coli* (Seymour S. Cohen), 746
- Glucose : Direct Oxidation of, by *Aerobacter* sp. (Dr. J. De Ley and S. Cornut), 515
  - Reversible Oxidation of, by Glucose Dehydrogenase (Prof. Harold J. Strecker and Dr. Seymour Korkes), 913
  - Utilization of Gluconate and, in Growing and Virus-infected *Escherichia coli* (Seymour S. Cohen), 746
- Glucose, Glutamate and Succinate Oxidation in Brain (Dr. H. Harris, Dr. E. M. Trautner and M. Messer), 914
- Glucose and Lysogenesis in *Bacillus megatherium* (H. L. Ehrlich and S. G. Knight), 658
- Glucose and the Terminal Amino Group of Lysine : Reaction between (R. S. Hannan and C. H. Lea), 744
- Glucose Dehydrogenase · Reversible Oxidation of Glucose by (Prof. Harold J. Strecker and Dr. Seymour Korkes), 913

α-Glucosidases in Yeast: Gene Function in the Homologous and Heterologous Induction of, by α-Glucosides (Prof. Shlomo Hestrin and Prof. Carl C. Lindegren) 913
Glucosides to Glucuronides: Catalytic Oxidation of (C. A. Marsh), 602
α-Glucosides: Gene Function in the Homologous and Heterologous Induction of α-Glucosidases in Yeast by (Prof. Shlomo Hestrin and Prof. Carl C. Lindegren), 913
Glucuronides: Catalytic Oxidation of Glucosides to (C. A. Marsh), 602
Glutamate and Succinate Oxidation in Brain: Glucose, (Dr. H. Harris, Dr. E. M. Trautner and M. Messer), 914
Gold: Change of Resistivity of, by Cold-working at Liquid-Air Temperature and its Recovery by Temporary Heating (Prof. M. J. Druyvesteyn and J. A. Manintveld), 868
  Stereochemistry of (R. S. Nyholm), 705
'Golgi Substance': The (Dr. John R. Baker), 1089
  Observations of the, with the Electron Microscope (Dr. A. J. Dalton), 244
Gorilla: The Anatomy of the (The Studies of Henry Cushier Raven), arranged and edited by William King Gregory, *review*, 926
Government: The Science and Art of (Lord Hankey), 571
Government (Local): Management Problems and (T. H. Hawkins), 553
Government Responsibility in Civilian Scientific Research, 481
Government Scientific Organization in the Civilian Field, 482
Gram Reaction: Localization of Bacterial Nucleic Acids and Mechanism of the (Hemer Hoffman), 464
Gran Chaco: Life in the, *review* by Prof. James Ritchie, 260
  A Naturalist in the (Sir James Graham Kerr), *review* by Prof. James Ritchie, 260
Granitization: Acid Front in (E. Venkayya), 79
Granular Forms of the Bovine Tubercle Bacillus: Nature and Infectivity of (Dr. E. M. Brieger, Dr. J. A. R. Miles, Dr. V. E. Cosslett and R. W. Horne), 96
Granules of the Islets of Langerhans: Fluorochromy as an Aid in the Resolution of the Specific (Dr. W. Stanley Hartroft), 1000
Graphite with Chromyl Chloride and Chromyl Fluoride: Lamellar Compounds of (R. C. Croft and R. G. Thomas), 32
Grasshoppers: Formation of Green Pigment in (Selahattin Okay), 254
Grassland and Grassland Products (Prof. Stephen J. Watson), *review* by Sir George Stapledon, 1013
Gratings: Diffraction (Optical Group of the Physical Society Symposium on), 67
Gravimetric Estimation of the Carboxylic Acid Group in Cellulose (J. Farrar, Dr. S. M. Neale and G. R. Williamson), 566
Gravitation in Kinematic Relativity (Prof. A. G. Walker), 961
Great Britain: Cancer Research in, 417
  Census of Woodlands in (Forestry Commission, Forest Record No. 3), 1026
  Cereal Varieties in (R. A. Peachey), *review* by J. S. L. Waldie, 531
  Chemical Industry in, 502
  Civil Administration in, *review* by R. Brightman, 310
  The Coal Industry of, 982
  Culex (Culex) torrentium Martini, a Mosquito New to (P. F. Mattingly), 172
  Development of Atomic Energy in, 61
  Higher Technological Education in (British Association, Section L (Education), Discussion on), 458
  Higher Technological Education in, 543
  Labour Turnover and Absence in, under Full Employment (Prof. E. H. Phelps Brown), 993
  Library Service in—Annual Conference of the Library Association, 329
  The Littoral Fauna of (Dr. N. B. Eales), second edition, *review* by Dr. D. P. Wilson, 51
  Petroleum Consumption and Production in (Petroleum Information Bureau Pamphlet on), 412
  Scientific and Learned Societies of, 57th edition, *review*, 218
  Soil Survey of, 1105
  Student Health in, 503
  Technical and Technological Education in, 709
  Universities of—Financial and Population Statistics for 1949–50, 622
  Volume Tables for Estimating Timber in, 111

Hen: Transfer of Bacterial Antibodies from the, to the Chick (A. Buxton), 657
Hen's Egg: Proteolytic Activity in, prior to Incubation (Hadar Emanuelsson), 958
Hen's Eggs (Embryonated): Cultivation of Canine Hepatitis Virus in, and its subsequent Transmission to Dogs (Dr. J. A. R. Miles, H. B. Parry, Dr. N. M. Larin and H. Platt), 699
Heparin as a Main Component of the 'Third Factor' involved in the Virulence-enhancing Action of Hog Gastric Mucin: Identification of a (Dr. H. Smith), 563
Hepatitis Virus (Canine): Cultivation of, in Embryonated Hen's Eggs and its subsequent Transmission to Dogs (Dr. J. A. R. Miles, H. B. Parry, Dr. N. M. Larin and H. Platt), 699
Hepatitis Virus and Antiserum (Canine): Preparation of the Specific Purified Antigen of, for Serological Studies (Dr. N. M. Larin), 745
n-Heptane Cyclizations: Activity of the Chromium–Aluminium Oxide Catalyst System in the Nitrile–Diene and (Dr. G. J. Janz and P. J. Hawkins), 387
Hertz (Heinrich) Premium of the British Institution of Radio Engineers awarded to R. Kompfner, 413
Heterocyclic Compounds (edited by Robert C. Elderfield), Vols. 1 and 2, *review* by Dr. James D. Loudon, 618
  Chemistry of, *review* by Dr. James D. Loudon, 618
Hexane: Inert Gas Effects in the Oxidation of (N. J. H. Small and Prof. A. R. Ubbelohde), 201
High-Power Photo-Flash Tubes (Prof. M. Laporte), 552
Histamine: Effect of, on the Activity of Hyaluronidase (Dr. F. Seelich and P. Hübl), 1125
Histamine Release by Anaphylatoxin (Prof. M. Rocha e Silva, O. Bier and M. Aronson), 465
Histochemical Evidence of the Presence of Acid Phosphatase-Positive and -Negative Cell Islets in the Adrenal Medulla of the Rat (Dr. O. Eränkö), 250
Histological Changes in the Epithelium of the Small Intestine during Protein Absorption in the New-born Animal (Dr. H. B. Comline, H. E. Roberts and D. A. Titchen), 84
Histone prepared from Rat Liver Desoxypentosenucleoprotein: Composition of (Robert Brunish, DeLores Fairley and Prof. J. Murray Luck), 82
Historical Approach to Bacterial Cytology, *review* by Dr. K. A. Bisset, 439

Hochfrequenztechnik : Die elektromagnetische Schirmung in der Fern- und (Dr. Heinrich Kaden), *review* by R. E. Burgess, 717
Hog Adrenals : Isolation of 17-Hydroxycorticosterone and 17-Hydroxy-11-dehydrocorticosterone from (P. B. Baker, F. Dobson and S. W. Stroud), 114
Hog Gastric Mucin : Identification of a Heparin as a Main Component of the 'Third Factor' involved in the Virulence-enhancing Action of (Dr. H. Smith), 563
Home Counties : The Municipal Library System of London and the (edited by James D. Stewart), 500
Home Life of an Astronomer, *review* by Prof. F. J. M. Stratton, 440, 1008 ; (Mrs. Margaret Wilson), 1007
l'Homme et des Animaux Quaternaires découvertes en Belgique : Les représentations de (Prof. Francois Twiesselmann), 1026
Hormone (Moulting) : Source of, in *Rhodnius* (Dr. V. B. Wigglesworth), 558
Hormones : Growth, of Rice Grains Germinated at Different Temperatures (Prof. S. M. Sircar and T. M. Das), 382
Horse-sickness Virus Vaccine (African) : An Improved Diluent for the Production of (A. Polson, J. Dent, S. M. Lawrence and P. J. van Rooy), 655
Hosts : Effect of, on the Egg Coloration of the Parasite *Bracon gelechiae* Ashmead (Braconidae), (G. C. Sen Gupta), 793
Houseflies : Mechanism of Resistance to Insecticide in (Dr. J. R. Busvine), 193
Hoxne, Suffolk : The Interglacial Beds at (D. F. W. Baden-Powell), 701
Huggins Type : A Method for making Accurately Reproducible Masks of the (Barton Howell, Carl J. Christensen and Dan McLachlan, Jun.), 282
Hughes Medal for 1951 of the Royal Society awarded to Prof. H. A. Kramers, 856, 1018
Human Beings : The Human Use of—Cybernetics and Society (Prof. Norbert Wiener), *review* by F. I. G. Rawlins, 442
Human Blood at Microwave Frequencies : Dielectric Behaviour of (Dr. H. F. Cook), 247
Human Blood Group Antigen *Jk^a* : Inheritance of the (Dr. R. R. Race, Dr. Ruth Sanger, Dr. Fred H. Allen, Jun., Dr. Louis Diamond and Bevely Niedziela), 207
Human Body : Methylation of a Phenolic Hydroxyl Group in the (Prof. N. F. Maclagan and Dr. J. H. Wilkinson), 251
Human Factor in Industry (Safety, Health and Welfare Museum Exhibition to remain open), 500
Human Fat and Muscle: Thermal Conductivity of (Dr. H. Stafford Hatfield and Dr. L. G. C. Pugh), 918
Human Plasma : Factor *Rh* Activity in (Dr. Ellsworth C. Dougherty), 880
Human Problems of the Scottish Highlands, 191
Human Relations in Industry, 841
  Christianity and (Sir George Schuster), 842
Human Skin and in Finger Nails : Occurrence of Thin Membranes in the Surface Layers of (Gösta Lagermalm, Bo Philip and Joel Lindberg). 1080
Human Tissue and from Ox Ligament : Elastin from (Dr. David A. Hall), 513
Human Tooth: Transmutation in the (W. G. Armstrong and H. F. Atkinson), 695
Human Use of Human Beings—Cybernetics and Society (Prof. Norbert Wiener), *review* by F. I. G. Rawlins, 442
Humanism and Technology, *review* by Colonel H. D. Anthony, 530
Humanity and the Helm, *review* by F. I. G. Rawlins, 442
Humus : An Apostle of, *review* by Prof. R. H. Stoughton, 715
Hundred Years of Chemistry (Lord McGowan), 369
Hundred Years of Organic Chemistry (1851–1951), (Prof. A. R. Todd), 326
Hundred Years of Plant Morphology (Dr. H. Hamshaw Thomas), 312
Husbandry : English, from the Earliest Times to the Present Day (Robert Trow-Smith), *review* by Sir John Russell, 307
Hüttig's Adsorption Isotherm (Otto Theimer), 873
Hyalobiuronic Acid, from Hyaluronic Acid : Isolation of a Crystalline Disaccharide, (Maurice M. Rapport, Bernard Weissmann, Alfred Linker and Dr. Karl Meyer), 996
Hyaluronic Acid : Isolation of a Crystalline Disaccharide, Hyalobiuronic Acid, from (Maurice M. Rapport, Bernard Weissmann, Alfred Linker and Dr. Karl Meyer), 996
Hyaluronidase : Effect of Histamine on the Activity of (Dr. F. Seelich and P. Hübl), 1125
Hydnums : The Stipitate, of the Eastern United States (Prof. William Chambers Coker and Alma Holland Beers), *review* by E. J. H. Corner, 1015
Hydrodynamics, a Study in Logic, Fact and Similitude (Garrett Birkhoff), *review* by Prof. H. T. H. Piaggio, 93
Hydrodynamics : Unconventional, *review* by Prof. H. T. H. Piaggio, 93
Hydrogen (Radioactive) : Estimation of, as Tritiobutane in the Geiger Counter (Dr. R. F. Glascock), 121
Hydrogen on Nickel Catalysts : Activated Adsorption of (Dr. G. C. A. Schuit and N. H. de Boer), 1040
Hydrogen Evolution by *Trichomonas foetus* (Suzuoki-Ziro and Suzuoki-Tuneko), 610
Hydrogen Exhaustion and Explosions of Stars (Dr. G. Gamow), 72
Hydrogen Peroxide : Ferric-Ion Catalysed Decomposition of, and the Polymerization of Acrylonitrile (Dr. Adolf G. Parts), 79
  Reaction of Metmyoglobin with (Dr. P. George and D. H. Irvine), 164
Hydrogen Radiation of Wave-length 21 cm. in the Sun : Absence of (C. de Jager, Prof. M. Minnaert and C. A. Muller), 391
Hydrophilic Colloids : A Fast Continuous Electrodialyser for, and a Fast Continuous Electrodecanter for Hydrophobic Colloids (Prof. A. J. Rutgers and R. Swyngedouw), 727
Hydrophobic Colloids: A Fast Continuous Electrodialyser for Hydrophilic Colloids, and a Fast Continuous Electrodecanter for (Prof. A. J. Rutgers and R. Swyngedouw), 727
17-Hydroxy-11-dehydrocorticosterone from Hog Adrenals : Isolation of 17-Hydroxycorticosterone and (P. B. Baker, F. Dobson and S. W. Stroud), 114
17-Hydroxycorticosterone and 17-Hydroxy-11-dehydrocorticosterone from Hog Adrenals : Isolation of (P. B. Baker, F. Dobson and S. W. Stroud), 114
8-Hydroxyquinoline Derivatives : Antitubercular Activity of some (Prof. T. Urbanski, Prof. S. Slopek and Dr. J. Venulet), 29
Hygiene : Insects and (Dr. James Busvine), *review* by Dr. V. B. Wigglesworth, 354
Hygiene in Chemical Industry from the Point of View of the Manager, Technician and Operative : Safety and (Sindicato Vertical de Industrias Quimicas Conference on), 641
Hyperglycaemic Action of Blood from Animals treated with Growth Hormone (Dr. J. Bornstein, Dr. E. Reid and Prof. F. G. Young), 903
Hyperparathyroidism (Experimental) : Renewal of Bone Phosphate in (R. Zetterstrom and B. Engfeldt), 81
Hypophysis of the Guinea Pig : Inhibition of the, by Ultra-Sound Waves (Prof. V. H. Cicardo, Dr. A. A. Cappellino and Dr. E. Del Conte), 169
Hypotheses relating to the Brain–Mind Problem (Prof. J. C. Eccles), 53

ILLUMINANT : A Discharge, for Optical Systems capable of either Continuous or Flash Operation (E. J. G. Beeson and A. A. Webb), 1038
Illustration : Die naturwissenschaftliche (Claus Nissen), *review* by P. J. C., 486
Impurity found in Solutions of Radioactive Phosphorus : A Particulate (Dr. J. E. Hotchin), 200
Inactivation of Adrenotropic Hormone (ACTH) by Plasma (Dr. Max Reiss, F. E. Badrick, I. D. K. Halkerston and C. Pearce), 206
Incoherent X-Ray Scattering in Crystals : A New Method of Observing Compton and other (H. J. Grenville-Wells), 291
Incubation : Proteolytic Activity in Hen's Egg prior to (Hadar Emanuelsson), 958
India : The Feeding of Farm Animals in (Dr. P. E. Lander), *review* by Dr. John Hammond, 440
  Natural Products of, *review* by Sir John Simonsen, 618
  The Wealth of, Vol. 2, Part 1, Raw Materials ; Vol. 2, Part 2, Industrial Products, *review* by Sir John Simonsen, 618
India and South-east Asia : History of Science and Technology in (Dr. Joseph Needham), 64, 1048 ; (Dr. S. L. Hora), 1047
Indian Ocean (Tropical) : Sedimentation in the (W. R. Riedel), 737
Indian Soils (South) : *Fusaria* isolated from (Dr. C. V. Subramanian), 561
Indians (South American) : Handbook of (edited by Julian H. Steward), Vol. 6, *review* by Dr. G. H. S. Bushnell, 575
Indium Monofluorides : Ultra-Violet Absorption Spectra of Gallium and (D. Welti and R. F. Barrow), 161
Individual : Theism and the, *review* by F. I. G. Rawlins, 178
Individual and the Group : Inferiority Feelings in the (Oliver Brachfeld), translated from the French by Marjorie Gabain, *review* by Dr. Clifford Allen, 972
Indole Derivatives : Perhydroxylation of, by Osmium Tetroxide (D. W. Ockenden and Dr. K. Schofield), 603
Indoleacetic Acid : Photo-inactivation of the Plant Hormone, by Fluorescent Substances (Dr. Mario G. Ferri), 334
Indonesia : Recent Climatic Variations in (K. J. ten Hoopen and Dr. F. H. Schmidt), 428
Induction of α-Glucosidases in Yeast by α-Glucosides : Gene Function in the Homologous and Heterologous (Prof. Shlomo Hestrin and Prof. Carl C. Lindegren), 913
Induction Periods in Reactions of N-Halogenimides (Prof. P. Goldfinger, P. A. Gosselain and Prof. R. H. Martin), 30
Industrial Applications of Gasfilled Triodes (Thyratrons), (R. C. Walker), *review* by Dr. U. W. Arndt, 50
Industrial Designs : Copyright and (A. D. Russell-Clarke), *review* by R. G. Lloyd, 847
  Law of Copyright and *review* by R. G. Lloyd, 847
Industrial Efficiency : Education and, 129
Industrial Research : International Symposium on the Organization of Scientific and (Department of Scientific and Industrial Research), 814
Industrial Research in East Africa, 319
Industrial Research in Switzerland (Prof. Ronald S. Edwards and Charles La Roche), *review* by S. Brightman, 398
Industrial Undertaking : Functions of a Personnel Department in an (G. R. Moxon), 823
Industrial and Safety Problems of Nuclear Technology (edited by Prof. Morris H. Shamos and Prof. Sidney G. Roth), *review* by Sir John Cockcroft, 263
Industry : Christianity and Human Relations in (Sir George Schuster), 842
  Human Factor in (Safety, Health and Welfare Museum Exhibition to remain open), 500
  Human Relations in, 841
  Quakers in Science and (Dr. Arthur Raistrick), *review* by V. A. Eyles, 94
Industry (Nationalized) : The Men on the Boards, a Study of the Composition of the Boards of (Acton Society Trust), 130
Industry in Belgium : Scientific Research in, 420
Industry is Using the Microscope : How (Royal Microscopical Society Exhibition), 814
Industry of Starch : Chemistry and (edited by Dr. Ralph W. Kerr), second edition, *review* by Prof. R. H. Hopkins, 179
Infection of Clover Plants : Multiple, by Strains of the Nodule Organism in the Field (Kathleen J. Baird), 116
Infection with a Neurotropic Variant of Influenza Virus : Protection by Receptor-destroying Enzyme against (H. J. F. Cairns), 335
Inferiority Feelings in the Individual and the Group (Oliver Brachfeld), translated from the French by Marjorie Gabain, *review* by Dr. Clifford Allen, 972
Infertility (Male) : Thyroxine Therapy in (Dr. M. Maqsood), 466
Infertility and Sterility (American Society for the Study of Sterility prize for an essay on), 858
Infinite in Giordano Bruno (Sidney Greenberg), *review* by F. I. G. Rawlins, 848
PR-8 Influenza : Electron Microscopy of Chick Embryo Membrane infected with (Dr. Ralph W. G. Wyckoff), 651
Influenza Virus : Protection by Receptor-destroying Enzyme against Infection with a Neurotropic Variant of (H. J. F. Cairns), 335
Infra-Red : An Interference Spectrometer for the (J. H. Jaffe), 381
Infra-Red Spectra of Germanium Tetrafluoride : Raman and (A. D. Caunt, L. N. Short and Dr. L. A. Woodward), 557
Infra-Red Spectrometer (Littrow-type) : Improving the Performance of a (J. C. O. Rochester and Dr. A. E. Martin), 785

Inhaca Island, Mozambique: Marine Biological Station on (Mrs. Olive S. Tattersall), 946
Inheritance of the Human Blood Group Antigen *Jk*^{a} (Dr. R. R. Race, Dr. Ruth Sanger, Dr Fred H. Allen, Jun., Dr. Louis K. Diamond and Bevely Niedziela), 207
Inhibiting Compounds: Reduction of Static Electrification by means of (G. W. Graham), 871
Inhibition of the Biosynthesis of Tobacco Mosaic Virus by Thiouracil (Dr. Barry Commoner and Frank Mercer), 113
Inhibition by Colchicine: Bacterial Enzyme Preparations Oxidizing Inositol and their (Robert E. Franzl and Prof. Erwin Chargaff), 955
Inhibition of the Hypophysis of the Guinea Pig by Ultra-Sound Waves (Prof. V. H. Cicardo, Dr. A. A. Cappellino and Dr. E. Del Conte), 169
Inhibitory Action of Artificial Light on the Sexual Season of the Ewe (Dr. E. S. E. Hafez), 336
Inorganic Bases: Estimation of the Approximate Ionization Constants of (J. C. McGowan), 601
Inorganic Compounds: Structural Chemistry of (Prof. Walter Hückel), translated by Dr. L. H. Long, Vol. 1, *review* by Prof. E. G. Cox, 756
Inorganic Syntheses (edited by Ludwig F. Audrieth), Vol. 3, *review* by A. J. E. W., 399
Inositol: Bacterial Enzyme Preparations oxidizing, and their Inhibition by Colchicine (Robert E. Franzl and Prof. Erwin Chargaff), 955
Inositol, a Major Constituent of the Seminal Vesicle Secretion of the Boar (Dr. T. Mann), 1043
Insect Larvae: Body-Temperature of Small (F. L. Waterhouse), 340
Insect Pest of Coconuts and its relationship to certain Ant Species (M. J. Way), 302
Insect Physiology in relation to Applied Biology (Association of Applied Biologists Discussion on), 974
Insecticidal Deposits: Fly Reactions to—a New Test Technique (Dr. F. Baranyovits), 960
Insecticide: Mechanism of Resistance to, in Houseflies (Dr. J. R. Busvine), 193
Insecticides: Modern, and the Balance of Nature (Dr. D. Stewart MacLagan), 360
Insecticides for the Protection of Sheep against Blowfly Strike: A New Biological Method for Evaluating the Efficiency of (O. G. H. Fiedler and R. du Toit), 608
Insects and Hygiene (Dr. James Busvine), *review* by Dr. V. B. Wigglesworth, 354
Insemination: Artificial, of Birds (G. C. van Drimmelen), 726
Institutions: International, 797
Instructional Film Research in Pennsylvania (C. Denis Pegge), 775
Instrument Industries' Exhibition, British, 185
Instrument Maintenance: Courses and Examinations for (City and Guilds of London Institute), 145
Insulin: Stimulation by, of *in vitro* Fat Synthesis by Mammary Tissue studied with Carbon-14 and Tritium (Judith H. Balmain, Dr. S. J. Folley and Dr. R. F. Glascock), 1083
Intensity of Radio Stars: A Search for Long-Period Variations in the (M. Ryle and B. Elsmore), 555
Intensity Variation in Sunspots (Dr. R. Ananthakrishnan), 291
Intensive Production in Animals: Limits to (British Association, Section M (Agriculture), Symposium on), 490
Inter-Commonwealth Postgraduate Scholarships in Science, 938
Interference Spectrometer for the Infra-Red (J. H. Jaffe), 381
Interferometry (Multiple-Beam): Applications of (C. F. Bruce), 472
Interglacial Beds at Hoxne, Suffolk (D. F. W. Baden-Powell), 701
Internal Strains, and the Bauschinger Effect in Metals: Magnetic Properties, (N. H. Polakowski), 838
International Conference on Low Temperature Physics: *Proceedings of the*, 939
International Conference of Naval Architects and Marine Engineers on Shipbuilding, 415
International Conference on Science Abstracting: Final Report, 1105
International Conference on Ultrasonics (Royal Flemish Academy and Unesco), 106
International Congress on Analytical Chemistry, 368
International Congress on Astronautics: Second (British Inter-planetary Society), 369; (J. Humphries), 733
International Congress of Biochemistry: Second, 456
International Congress of Pure and Applied Chemistry: Twelfth (D. Hamer), 766
International Congress of Refrigeration: Eighth (Dr. G. G. Haselden), 806
International Co-operation in the Analyses of the Deep-Sea Cores collected by the Swedish Deep-Sea Expedition 1947–48 (C. D. Ovey), 148
International Institutions, 797
International Nature Conservation, 175
International Organization: National Administration and, a Comparative Survey of Fourteen Countries (International Institute of Administrative Sciences and Unesco), 797
International Survey of Training for Social Work (United Nations Department of Social Affairs), 544
International Symposium on the Organization of Scientific and Industrial Research (Department of Scientific and Industrial Research), 814
Internuclear Distances of Di-atoms: Prediction of (Dr. C. H. Douglas Clark), 911
Intestine (Small): Histological Changes in the Epithelium of the, during Protein Absorption in the New-born Animal (Dr. R. S. Comline, H. E. Roberts and D. A. Titchen), 84
Intramolecular Configuration: A Novel Connexion between Electrostatic Interaction and (Dr. G. Baddeley, Dr. G. Holt, Dr. N. H. P. Smith and F. A. Whittaker), 386
Intramolecular Overcrowding: X-Ray Crystallographic Measurements on some Compounds showing (E. Harnik, F. H. Herbstein and G. M. J. Schmidt), 158
Intraseasonal Growth Variation and Cultivation of Sugar-cane (Dr. C. V. Krishna Iyengar), 252
Invalidation of the Genus *Vaughaniella* (A. B. Cribb), 302
Inventions: Introduction to the Patenting of (Cecil Hollins), *review* by R. G. Lloyd, 973
Inventories of Apparatus and Materials for Teaching Science, Vol. 2, Universities (Unesco), 102
Ion (Nitrite): Dimensions of the (Mrs. M. R. Truter), 344
Ion-exchange Columns: Chromatography of Adrenotropic Hormone on (H. B. F. Dixon, Dr. Stanford Moore, M. P. Stack-Dunne and Prof. F. G. Young), 1044
Ionic Melts (Supercooled): Discontinuities in (Dr. N. N. Greenwood and R. L. Martin), 344
Ionization Constants (Approximate): Estimation of the, of Inorganic Bases (J. C. McGowan), 601
Ionizing Radiation: A Method of making Visible the Distribution of Activity in a Source of (Prof. W. V. Mayneord, R. C. Turner, S. P. Newbery and H. J. Hodt), 762
Ionizing Radiations: Effects of, upon Isolated Deoxyribosenucleoprotein Fibres (H. M. Rozendaal, W. D. Bellamy and T. H. Baldwin), 694
Ions (Complex): Dissociation of, in Non-Aqueous Solvents (Dr. F. P. Dwyer and N. A. Gibson), 787
Ireland (Northern): Inland Waterways of Great Britain and (compiled by Lewis A. Edwards), *review* by Dr. K. G. Fenelon, 399
Irish Soil Series: Selenium Toxicity associated with an (T. Walsh, G. A. Fleming, R. O'Connor and A. Sweeney), 881
Iron (Magnetized): Action of Dilute Sulphuric Acid on (Prof. G. Wagner and P. Blaha), 74
Iron/Sulphide Ratios in Corrosion by Sulphate-reducing Bacteria (C. J. P. Spruit and J. N. Wanklyn), 951
Irradiated Mice: Protective Action of Ethyl Alcohol on (Edith Paterson and Joyce J. Matthews), 1126
Irradiation (Ultrasonic): Effects of, on the Coagulation of Cellulosic Solutions (Viscose), (Dr. V. Tomberg), 292
Irradiation by X-Rays: Effect of, on the Exhalation of Carbon Dioxide by the Mouse (Prof. G. Hevesy and A. Forssberg), 692
Isabelline Shrike on the Isle of May, 939
Isolation of a Crystalline Disaccharide, Hyalobiuronic Acid, from Hyaluronic Acid (Maurice M. Rapport, Bernard Weissmann, Alfred Linker and Dr. Karl Meyer), 996
Isolation of Octadecan-1 : 18-diol from Spanish Broom (Dr. O. C. Musgrave, James Stark and Prof. F. S. Spring), 298
Isomeric Compounds: Effect of *cis*-Cinnamic Acid and some, on the Germination of Zygotes of *Chlamydomonas* (Prof. Franz Moewus and Basudev Banerjee), 561
Isomers: Geometrical, in a Series of Antihistamines (D. W. Adamson, P. A. Barrett, J. W. Billinghurst, A. F. Green and T. S. G. Jones), 204
Isopod, *Asellus meridianus* Racovitza, with Low Chromosome Number (S. Muldal), 1127
Isotopes (Lead): Superconductivity of (Mrs. Marianne Olsen), 245
Isotopes (Oxygen and Carbon): Relative Abundances of, in Carbonate Rocks (Dr. P. Baertschi), 288
Isotopes (Radioactive): Errors in Determination of Specific Activity and Turnover Rates of (Prof. A. H. Ennor and H. Rosenberg), 199
Isotopes (Stable): Separation of, by Electromagnetic Means (W. D. Allen), 451
Isotopic Carbon Tetrachlorides: Vapour Pressure of (Prof. D. H. Rank and R. E. Kagarise), 740
Israel: Flora of the Land of (Naomi Feinbrun and Michael Zohary), *review* by E. J. S., 51

JACOBSON'S ORGAN, *review* by Prof. F. J. Cole, 529
Jaina Legend in Old Gujarati, 939
Jamaica: A New Platyctenid Ctenophore from (Jessie J. Rankin), 1047
Japanese Monograph of Lichen Chemistry, *review* by Dr. J. C. Dacre, 889
Jaws of Mandibulate Arthropods: Comparative Studies on the (R. E. Snodgrass), 682
Joshi Effect: A Magnetic Analogue of the (M. R. Bhiday, V. G. Bhide and G. V. Asolkar), 1006

KÆMPFERITIN: Identity of Lespedin with (Prof. Shizuo Hattori), 788
Kalinga Prize for Scientific Popularization (established by M. B. Patnaik), 19
Kapingamarangi: Material Culture of (Te Rangi Hiroa) (Peter H. Buck), 770
Kenya: New Hosts of *Phytophthora Infestans* in (R. M. Nattrass and Moira Ryan), 85
Kenya Timbers: Catalogue of (S. H. Wimbush), 813
Keratin Fibres: Resistant Peripheral Membranes of the (Dr. E. H. Mercer), 824; (Dr. C. H. Bamford, Dr. A. Elliott and W. E. Hanby), 824
α-Keto-Acids: Enzymatic Conversion of the Stereoisomers of *iso*Leucine to the Corresponding (Dr. Alton Meister), 1119
  Transamination to Pyruvate and some other (E. V. Rowsell), 104
Ketoglutarate: Production of, by *Penicillium chrysogenum* (D. J. D. Hockenhull, G. D. Wilkin and F. G. Winder), 1043
α-Ketoglutaric Acids in Cultures of *Aspergillus niger* on various Substrates: Chromatographic Detection of Pyruvic, Dimethylpyruvic and (Dr. T. K. Walker, A. N. Hall and J. W. Hopton), 1042
Khmer Empire: The Ancient (Miss Kathleen Gough), 777
Kidd (*Jk*^{a}) Haemagglutinin: A Further Example of (Lois Hunter, Marion Lewis and Dr. Bruce Chown), 790
Kidney of Adult Rats: Relation between Polyploidy and the Amounts of Deoxynucleic Acid per Nucleus in the Liver and (Marion F. Harrison), 248
Kidney Citrate Levels in Nucleotide Shock (C. J. Threlfall, H. B. Stoner and Prof. H. N. Green), 297
Kidney Phosphatase: Coenzyme of (Prof. M. Lora Tamayo and A. M. Municio), 249
Kidney Slices: Rapid Rate of Turnover of Potassium Ions in (Dr. R. E. Davies and Dr. A. W. Galston), 700
Kinematic Relativity: Gravitation in (Prof. A. G. Walker), 961
Knoop Research Fellowship in Economics of the University of Sheffield awarded to D. C. Corner, 726
Knowledge: Trade Barriers to (Unesco), 437
Kolloidchemie: Kurzes Lehrbuch der (Dr. B. Jirgensons and Dr. M. Straumanis), *review* by Dr. D. P. Riley, 132
Kosambi's Formula: An Extension of (A. R. G. Owen), 208

LABORATOIRES: Bilingual Review of French Technology, No. 1, 454
Laboratory: Safety in the (Dunlop Rubber Co., Ltd., Manual on), 188

Labour Turnover under Full Employment (Dr. Joyce R. Long), 993
Lacertilia : Sacral Ribs of (Dr. Abdel Halim Kamel), 660
Lactational Physiology : Terminology for Use in (Dr. A. T. Cowie, Dr. S. J. Folley, B. A. Cross, Dr. G. W. Harris, Dora Jacobsohn and K. C. Richardson), 421
Lactobacilli : 'Lactobacillin', an Antibiotic from (Dorothy M. Wheater, Dr. A. Hirsch and Dr. A. T. R. Mattick), 659
'Lactobacillin', an Antibiotic from Lactobacilli (Dorothy M. Wheater, Dr. A. Hirsch and Dr. A. T. R. Mattick), 659
β-Lactoglobulin Crystals : Crystal Structure of a Low Molecular Weight Protein—Electron Microscopy of (Dr. I. M. Dawson), 241
β-Lactoglobulin Crystals (Dry) : Crystal Structure of a Low Molecular Weight Protein—Structure of (Dr. D. P. Riley), 242
Laity : Psychology and the (Prof. C. A. Mace), 231
Lamb (New-born) : Absorption of Anti-Nematode Antibodies from Ewe's Colostrum by the (Daisy B. Filmer and T. J. McClure), 170
Lambs : Prevention of Swayback Symptoms in, by administration of Copper Sulphate to the Pregnant Ewe (Dr. George Dunlop), 728
Lambs (Australian Merino) : Birth Coats of (P. G. Schinckel), 698
Lamellar Compounds of Graphite with Chromyl Chloride and Chromyl Fluoride (R. C. Croft and R. G. Thomas), 32
Land (British) : Productivity of (Report of the Rural Reconstruction Association), 187
Land of Britain (L. Dudley Stamp), second edition, *review* by Sir John Russell, 803
  Planning the, 967
Land Utilization : Planning and, 45
Land Utilization in Australia (Prof. C. M. Wadham and Prof. G. L. Wood), second edition, *review*, 928
Langerhans (Islets of) : Fluorochromy as an Aid in the Resolution of the Specific Granules of the (Dr. W. Stanley Hartroft), 1000
Langley Memorial Prize of the London School of Hygiene and Tropical Medicine awarded to Dr. J. H. Gerber, 899
Laplace Integral (Two-Sided) : Operational Calculus based on the (Dr. Balth van der Pol and Dr. H. Bremmer), *review* by J. H. Pearce, 133
Lattice Constants of Cr_2O_3 near the Curie Temperature : Changes in (Miss Selma Greenwald), 379
Layman : Science and the, 213
Lead Isotopes : Superconductivity of (Mrs. Marianne Olsen), 245
Leadership : Education and (Dr. Eric James), 754
Leadership in the Modern State, 571
Leadership in the Welfare State, 1093
Leadership Training in the Universities (Sir Walter Moberly), 769
Leadership, Education and Technology, 753
Leaf Scar as an Avenue of Infection for the Cherry Bacterial Canker Organism, *Pseudomonas mors-prunorum* Wormald (J. E. Crosse), 560
Learned Societies of Great Britain : Scientific and, 57th edition, *review*, 218
Learning Abilities of Birds (W. H. Thorpe), 552
Leave for University Teachers : Recurrent Long, 509
Lectotypes in Mycology, a Taxonomic Proposal (E. J. H. Corner), 1031
Leeward and Line Islands : Fish Collections from the, 1027
Leisure : Children's, 649
Lespedin with Kaempferitrin : Identity of (Prof. Shizuo Hattori), 788
*iso*Leucine : Enzymatic Conversion of the Stereoisomers of, to the Corresponding α-Keto-Acids (Dr. Alton Meister), 1119
Leucocytes (Rabbit Polymorphonuclear) : Ali-esterase of (Miss Esther Wong), 80
Leverhulme Research Fellowships 1951, 19
Liberties of the Mind (Charles Morgan), 306
Liberty : Democratic Planning and, *review* by R. Brightman, 844
  The Logic of (Prof. Michael Polanyi), *review* by R. Brightman, 844
Library Service in Great Britain—Annual Conference of the Library Association, 329
Library System : Municipal, of London and the Home Counties (edited by James D. Stewart), 500
Lichen Chemistry : Japanese Monograph of, *review* by Dr. J. C. Dacre, 889
Lichen Substances : Chemistry of (Prof. Yasuhiko Asahina and Prof. Shoji Shibata), *review* by Dr. J. C. Dacre, 889
Lichens : Biochemistry in the Taxonomy of (I. Mackenzie Lamb), 38
Life of the Shore and Shallow Sea (Dr. Douglas P. Wilson), second edition, *review* by Dr. N. B. Eales, 1014
Life and Work in Extreme Environmental Conditions (British Association, Section A (Mathematics and Physics), Discussion on), 363
Life-time of μ-Mesons : Determination of the Mean (Dr. J. Pernegr), 1004
Light : Effect of, on the Germination of Watercress Seeds (H. W. Howard and A. G. Lyon), 253
Light (Artificial) : Inhibitory Action of, on the Sexual Season of the Ewe (Dr. E. S. E. Hafez), 336
Light (Polarized) : Effect of Orientation on the Metallic Reflection of (D. H. Woodard and E. L. Bronson), 742
Light Energy : Transfer of, within the Pigment Systems present in Photosynthesizing Cells (L. N. M. Duysens), 548
Light Filters of Coloured 'Perspex' (Prof. E. J. King and S. Ventura), 702
Light-scattering Studies on Penicillin G Solutions (C. S. Hocking), 423
Light and Sound (M. Nelkon), *review*, 7
d-Limonene (Oxidized) : Effect of, on Micro-organisms (I. Zukerman), 517
Line Islands : Fish Collections from the Leeward and, 1027
Lipolytic Mould : Mould Lipase—Effect of Addition of Vitamins and Sterol to the Cake Medium on the Growth and the Activity of the (Dr. C. Ramakrishnan and Prof. B. N. Banerjee), 917
Liquid-Air Temperature : Change of Resistivity of Gold by Cold-working at, and its Recovery by Temporary Heating (Prof. M. J. Druyvesteyn and J. A. Manintveld), 868
Liquid Media : Mixing and Agitating in (Institution of Chemical Engineers Conference on), 376
Liquids : Chemical Effects in, due to α-Particle Irradiation (Prof. P. I. Dee and E. W. T. Richards), 736
  A Relationship between Heat Conductivity and Viscosity of (Dr. S. R. Mohanty), 42
Liquids and Gases : A Highly Sensitive Phase-Contrast Refractometer for (Erik Ingelstam), 960
Lithium-7 Nucleus (C. M. Class and Prof. S. S. Hanna), 429
Lithium Hydride : A Quantum Mechanical Study of (Inga Fischer), 1002
Little People of Oceania : The Menehune of Polynesia and other Mythical (Katharine Luomala), 639
Littrow-type Infra-Red Spectrometer : Improving the Performance of a (J. C. O. Rochester and Dr. A. E. Martin), 785
Liver : Effect of Vitamin B_{12} on the Synthesis of Protein and Nucleic Acids in the (M. R. Sahasrabudhe and M. V. Lakshminarayan Rao), 605
  A Phosphate Ester of a Tricarboxylic Acid in (S. Rapoport and Robert H. Wagner), 295
Liver of the Rat : Effects of a Protein-free Diet on the Alkaline and Acid Phosphatase Activity of the (J. O. Ely and M. H. Ross), 323
Liver and Kidney of Adult Rats : Relation between Polyploidy and the Amounts of Deoxynucleic Acid per Nucleus in the (Marion F. Harrison), 248
Liver and Serum of Male and Female Rats : Effect of a Single Injection of Carbon Tetrachloride upon the Activity of the Pseudo-cholinesterase in the (Lucy M. Brown and Marion F. Harrison), 83
Llama : The Eosinophil Cell as seen in the (Dr. F. Duran-Jorda), 1129
Locust Swarms : Weather and the Movements of—a New Hypothesis (Dr. R. C. Rainey), 1057
Logic of Adaptation, *review* by Prof. C. H. Waddington, 1013
Logic of Liberty (Prof. Michael Polanyi), *review* by R. Brightman, 844
London and the Home Counties : The Municipal Library System of (edited by James D. Stewart), 500
London's Picturesque Cloud Scenery (L. C. W. Bonacina), 1105
London–Birmingham Television-Cable System (T. Kilvington, F. J. M. Laver and H. Stanesby), 1034
Long Ashton Research Station Field Day (R. W. Marsh), 375
Longevity of *Nelumbo* Fruits, 905
Lotmar–Picken X-Ray Diagram of Dried Muscle (Dr. C. H. Bamford and W. E. Hanby), 1085
Lotmar–Picken X-Ray Diffraction Diagram of Muscle (Prof. Richard S. Bear and Dr. Cecily M. M. Cannan), 684
Louse (Sucking) : Spermatheca in (D. Mukerji and P. Sen Sarma), 612
Low-Frequency Dielectric Absorption and Direct-Current Conductivity in Quinol (J. S. Dryden and Dr. R. J. Meakins), 1121
Low-Temperature Physics (Dr. B. Bleaney and Dr. R. Bowers), 807
Low-Temperature Physics, International Conference on : *Proceedings* of the, 939
Loyalty of Free Men (Alan Barth), 1051
Loyalty and Science : Security, (Prof. Walter Gellhorn), 305
Lumbrical : The Rabbit, a New Isolated Mammalian Nerve-Muscle Preparation (D. J. Jenden, K. Kamijo and D. B. Taylor), 880
Lymphatic System (Mammalian) : Development of the (N. K. Balankura), 196
Lymphocytes *in vitro* : Effect of Antilymphocytic Serum on Suspensions of (Dr. Michael Woodruff and Bruce Forman), 35
Lysergic Acid Diethylamide : Psychological and Biochemical Effects of (Dr. W. Mayer-Gross, Dr. W. McAdam and Dr. J. W. Walker), 827
Lysine : Reaction between Glucose and the Terminal Amino Group of (R. S. Hannan and C. H. Lea), 744
Lysogenesis in *Bacillus megatherium* : Glucose and (H. L. Ehrlich and S. G. Knight), 658

MACHINES : Brains and, *review* by Prof. S. Zuckerman, 1095
McNair (John Calvin) Lectures (Edmund W. Sinnott), *review* by Prof. C. H. Waddington, 970
Magmas : Minerals and—Studies at High Temperatures and Pressures (E. D. Lacy), 537
Magnetic Analogue of the Joshi Effect (M. R. Bhiday, V. G. Bhide and G. V. Asolkar), 1006
Magnetic Field : Effect of a, on the Propagation of Sound Waves in a Ferromagnetic Material (J. de Klerk), 963
Magnetic Properties, Internal Strains, and the Bauschinger Effect in Metals (N. H. Polakowski), 838
Magnetic Storms and Auroras : The Theory of (Prof. Sydney Chapman), 86
Magnetic Susceptibility of Ovalene : Electrical Conductivity and (Prof. Hideo Akamatu, Hiroo Inokuchi and Takashi Handa), 520
Magnetism : Electricity and, Classical and Modern (Dr. G. B. Deodhar and K. S. Singwi), *review* by A. H., 717
  Remanent, of Rocks and the History of the Geomagnetic Field (J. Hospers), 1111
Makdougall–Brisbane Prize (1948–50) of the Royal Society of Edinburgh presented to Prof. James Small, 61
Malachite Green Techniques : Egg-Shell Formation in Trematodes and Cestodes as demonstrated by the Methyl or (Dr. J. D. Smyth), 322
Malaria (World) : Fall in (E. J. Pampana), 499
Malarial Strains : A 2 : 4-Diamino Pyrimidine in the Treatment of Proguanil-resistant Laboratory (L. M. Rollo), 332
Malaya : Effects of DDT upon Different Species of Mosquitoes in (J. A. Reid), 863
Male and Female Elements in Fertilization : Activation and the Correlation between (C. R. Austin), 558
Malt Extract : Fermentation of (Mary P. English), 391
Mammalian Lymphatic System : Development of the (N. K. Balankura), 196
Mammalian Nerve-Muscle Preparation : The Rabbit Lumbrical, a New Isolated (D. J. Jenden, K. Kamijo and D. B. Taylor), 880
Mammals : Factors Concerned in Fertility of, 286
  Natural History—Birds and (David Seth-Smith), *review* by M. A. C. Hinton, 136
Mammals in New Zealand : Blood Parasites of (Dr. M. Laird), 640
Mammary Tissue studied with Carbon-14 and Tritium : Stimulation by Insulin of *in vitro* Fat Synthesis by (Judith H. Balmain, Dr. S. J. Folley and Dr. R. F. Glascock), 1083
Man : *ABO* Blood Groups and Sex-Ratio at Birth in (Dr. L. D. Sanghvi), 1077
  Diffusion Respiration in (H. Enghoff, M. H:son Holmdahl and L. Risholm), 830
  Early, in the New World (Kenneth Macgowan), *review* by Dr. G. H. S. Bushnell, 92
  Genetics and the Races of (Prof. William C. Boyd), *review* by Dr. J. C. Weiner, 1054
Man the Maker (R. J. Forbes), *review* by Colonel H. D. Anthony, 530
Man in Britain : A Natural History of (Prof. H. J. Fleure), *review* by M. C. Burkitt, 757
Man in Britain Throughout the Ages, *review* by M. C. Burkitt, 757

TITLE INDEX

Man's Control of Wild Animals (David Seth-Smith), 26
Management Problems and Local Government (T. H. Hawkins), 553
Management Studies : Certificates and Diplomas in (British Institute of Management), 500
Mandibulate Arthropods : Comparative Studies on the Jaws of (R. E. Snodgrass), 682
Mankind : Geography in the Service of (E. O. Gifford), 314
Manpower Shortage in the United States (Dr. M. H. Trytten), 725
Manuscript for Publication : Preparation of, 857
Marginal Land Farming : Problems of (British Association, Sections F (Economics) and M (Agriculture), Discussion on), 457
Marine, Freshwater and Field Stations : Zoology at the (British Association, Section D (Zoology), Discussion on), 546
Marine Animals and Plants, *review* by Dr. N. B. Eales, 1014
Marine Spiny Crayfish *Jasus lalandii* (Milne Edwards) : A Study of the (C. A. Bradstock), 640
Maritime Meteorology (Geophysical Institute of the University of Genoa Conference on), 102
Marriage (Kenneth Walker), *review* by Dr. Eliot Slater, 1055
  Education for, *review* by Dr. Eliot Slater, 1055
Marsilea spp.—Materials for the Experimental Study of Morphogenesis (A. Allsopp), 301
Masks of the Huggins Type : A Method for making Accurately Reproducible (Barton Howell, Carl J. Christensen and Dan McLachlan, Jun.), 282
Mass Ratios in Nuclear Emulsions : Measurements of (Prof. Sten von Friesen and Krister Kristiansson), 377
Masses : The Clear Representation of Very Small (N. W. Pirie), 1008
Masters Memorial Lectures of the Royal Horticultural Society (M. B. Crane), 376
Mathematical Colloquium : Fifth (University of St Andrews), 321
Mathematical Statistics : Contributions to (Prof. R. A. Fisher), review by Dr. F. Yates, 308
Mathematical Tables : Chambers's Shorter Six-Figure (Dr. L. J. Comrie), *review* by Prof. W. G. Bickley, 441
Mathematicians : Dynamics for, *review* by Prof. T. G. Cowling, 714
Mathematics at the College of Aeronautics, 897
Mathematics of Non-Linear Vibrations, *review* by Prof. H. T. H. Piaggio, 49
Mating Behaviour in *Drosophila melanogaster* : Antennae and (Dr. Michael Begg and Elsie M. Packman), 953
Matter : Measurements of Mind and (Dr. G. W. Scott Blair), *review* by G. R. Noakes, 136
Maxwell (Clerk) Premium of the British Institution of Radio Engineers awarded to D. W. Heightman, 413
May (Isle of) : Isabelline Shrike on the, 939
Measure and Measurable Functions, *review* by Prof. H. T. H. Piaggio, 260
Measure Theory (Prof. Paul R. Halmos), *review* by Prof. H. T. H Piaggio, 260
Measuring the Atomic Heats of Gases : A New Method for (Prof. H. S. Gregory and I. I. Sheriff), 1123
Meat Production (Centre National de Coordination des Études et Recherches sur la Nutrition et l'Alimentation Symposium on), 940
Mécanique : Méthodes de calcul dans des problèmes de (Colloques Internationaux du Centre National de la Recherche Scientifique, 14), Marseille, 30 Mars–6 Avril 1948, Paris, 8–9 Avril 1948, *review* by H. T. H. P., 621
Mechanical Properties of Metals at High and Low Temperatures, *review* by Prof. F. C. Thompson, 49
Mechanical Properties of α-Solid Solutions of Copper, with Zinc, Gallium, Germanium and Arsenic (Dr. N. P. Allen, T. H. Schofield and A. E. L. Tate), 378
Mechanical Properties and Structure of Sol-type and Gel-type Gelatine Films (E. Bradbury and C. Martin), 837
Mechanical and Electrical Systems : Nonlinear Vibrations in (J. J. Stoker), *review* by Prof. H. T. H. Piaggio, 49
Mechanics (James E. Boyd and Prof. Percy W. Ott), third edition, *review*, 532
Mechanism of the Gram Reaction . Localization of Bacterial Nucleic Acids and (Heiner Hoffmann), 464
Medical Botany (Dr. Alexander Nelson), *review* by G. E. H Foxon, 262
Medical Education in Turkey (Prof. F. Nafiz Uzluk), 821
Medical Research in East Africa, 898
Medical Science . Travelling Scholarships in (Medical Research Council Awards), 189
Medicinal Chemistry (Prof. Alfred Burger), Vol. 1, *review* by Prof. J. W. Cook, 438
Medicine : Advances in, *review* by Sir Lionel Whitby, 529
  Annual Review of (edited by Windsor C. Cutting and Henry W. Newman), Vol. 2, *review* by Sir Lionel Whitby, 529
  British, and the Continent, 1600–1850 (Wellcome Historical Medical Museum Exhibition), 867
  Organic Chemistry in the Service of (British Association, Section B (Chemistry), Symposium on), 402
  Rockefeller Travelling Fellowships in (Medical Research Council Awards), 189
Melandrium dioicum (L. emend.) Coss. & Germ.: Cytology of the Ecotypes of Dioecious (Dr. H. G. Baker and W. Jackson), 747
Melanogenesis · Tyrosinase and Polyphenoloxidase—the Role of Metallic Ions in (Dr. Denis Kertész), 697
Meldola Medal of the Society of Maccabaeans, 545
Membrane in Wool : A Resistant (Dr. P. Alexander), 1081
Membranes : Resistant Peripheral, of the Keratin Fibres (Dr. E. H. Mercer), 824 ; (Dr. C. H. Bamford, Dr. A. Elliott and W. E. Hanby), 824
Membranes (Thin) : Occurrence of, in the Surface Layers of Human Skin and in Finger Nails (Gösta Lagermalm, Bo Philip and Joel Lindberg), 1080
Men (Free) : The Loyalty of (Alan Barth), 1051
Men on the Boards, a Study of the Composition of the Boards of Nationalized Industry (Acton Society Trust), 130
Menehune of Polynesia and other Mythical Little People of Oceania (Katherine Luomala), 639
Meson Production : Evidence of Multiple (J. B. Swan), 73
Mesons in Photographic Emulsions : Density of Tracks of Protons and (Torsten Gustafson), 377
μ-Mesons : Determination of the Mean Life-time of (Dr. J. Pernegr), 1004
Metabolism (Oxidative) : Chemistry o the, of certain Aromatic Compounds by Micro-organisms (Dr. W. Charles Evans, B. S. W. Smith, Prof. R. P. Linstead and Dr. J. A. Elvidge), 772
Metabolism in *Daphnia magna* : A Case of Disturbed (Edw. Flückiger), 211
Metabolism of Tryptophan : Intermediary (Dr. C. E. Dalgleish, Dr. W. E. Knox and Dr. A. Neuberger), 20
Metabolite of 'Paludrine' with High Antimalarial Activity (Dr. H. C. Carrington, Dr. A. F. Crowther, Dr. D. G. Davey, Dr. A. A. Levi and Dr. F. L. Rose), 1080
Metal Physics : Progress in (edited by Dr. Bruce Chalmers), Vol. 2, *review* by Dr. W. Hume-Rothery, 801
  Recent Developments in, *review* by Dr. W. Hume-Rothery, 801
Metal Spectroscopy (F. Twyman), *review* by Dr. A. G. Gaydon, 5
Metal-work in Britain : Early Celtic (Sir Cyril Fox), 229
Metallic Ions in Melanogenesis : Tyrosinase and Polyphenoloxidase—the Role of (Dr. Denis Kertész), 697
Metallic Materials at Low Temperatures : The Properties of (P. Litherland Teed), *review* by Prof. F. C. Thompson, 49
Metallic Oxides with the Structure of High-speed Steel Carbide (Nils Karlsson), 558
Metallic Reflexion of Polarized Light : Effect of Orientation on the (D. H. Woodard and E. L. Bronson), 742
Metallurgical Abstracts (General and Non-Ferrous), Vol. 16, 1948–49 (edited by Lieut.-Colonel S. C. Guillan and Major W. G. Askew), *review* by Dr. W. Hume-Rothery, 1016
Metallurgical Applications of the Electron Microscope (Institute of Metals, in association with the Chemical Society, the Faraday Society, the Institute of Physics, the Institution of Electrical Engineers, the Iron and Steel Institute, the Physical Society, and the Royal Microscopical Society, Symposium on), *review* by F. C. T., 179
Metallurgical Congress : World, 275
Metallurgy : The Electron Microscope in, *review* by F. C. T., 179
Metallurgy (Powder) : Science and Technology of, *review* by H. W. Greenwood, 133
  Treatise on (Dr. Claus G. Goetzel), *review* by H. W. Greenwood, 133
Metallurgy (Prehistoric) : Notes on the, of Copper and Bronze in the Old World (H. H. Coghlan), *review* by M. C. Burkitt, 531
Metals : Formula for Creep Curves of (Prof. Ryukiti Robert Hasiguti and Tosiro Owadano), 706 ; (Prof. E. N. da C. Andrade), 1007
  Magnetic Properties, Internal Strains, and the Bauschinger Effect in (N. H. Polakowski), 838
  Mechanical Properties of, at High and Low Temperatures, *review* by Prof. F. C. Thompson, 49
  Properties of, at Elevated Temperatures (George V. Smith), *review* by Prof. F. C. Thompson, 49
Metals (Buried) : Corrosion of (Iron and Steel Institute, in conjunction with the British Iron and Steel Research Association and the Corrosion Group of the Society of Chemical Industry, Symposium on), 456
Metals (Liquid) : Surface Tension of (Dr. R. A. Weale), 343 ; (Dr. S. W. Smith), 343
Metals and Alloys (British Association, Sections B (Chemistry) and G (Engineering), Discussion on), 414
Meteorology : A Hundred Years of (Sir David Brunt), 225
  Maritime (Geophysical Institute of the University of Genoa Conference on), 102
Methanol on Coal : Absorption of Water and (J. A. Lecky, W. Keith Hall and Robert B. Anderson), 124
Methyl or Malachite Green Techniques: Egg-Shell Formation in Nematodes and Cestodes as demonstrated by the (Dr. J. D. Smyth), 322
Methyl-Histidine (Urinary) : Dietary Origin of (S. P. Datta and H. Harris), 296
2-Methyl-3 : 4-Benzphenanthrene : A Novel Synthesis of (Dr. S. M. Mukherji and P. N. Rao), 1041
Methylamine : Protective Action of, against X-Irradiation (Prof. Z. M. Bacq and A. Herve), 1126
Methylation of a Phenolic Hydroxyl Group in the Human Body (Prof. N. F. Maclagan and Dr. J. H. Wilkinson), 251
N-Methylation : Paper Partition Chromatography of some Organic Bases by the method of (Tatsuo Kariyone and Dr. Yohei Hashimoto), 739
Metmyoglobin with Hydrogen Peroxide . Reaction of (Dr. P. George and D. H. Irvine), 164
Metric Conversion Tables : Warne's (designed by Otto Klein), *review*, 136
Mica : Epitaxis of Rubidium Iodide on a Barium Stearate Substrate deposited on (A. A. Fuller), 471, 899
Mica (Natural and Synthetic) : Transmission of, in the Ultra-Violet (P. Popper), 1119
Mice : Action of Terramycin and Chloromycetin on Cholera Vibrio in (Dr. E. Olejnik and S Davidovitch), 654
  Antituberculous Effect of certain Surface-Active Polyoxyethylene Ethers in (Dr. J. W. Cornforth, Dr. P. D'Arcy Hart, R. J. W. Rees and J. A. Stock), 150
Mice (Adult) : Differentiation of Skeletal Structures from Mouse Embryo Mince in the Peritoneum of (Theodore S. Hauschka), 1130
Mice (Irradiated): Protective Action of Ethyl Alcohol on (Edith Paterson and Joyce J. Matthews), 1126
Micellar Orientation in the Secondary Wall of Conifer Tracheids · Helical Thickenings and (Dr. A. B. Wardrop and H. E. Dadswell), 610
Microbiological Oxidation of Ammonium and Thiocyanate Ions in Soil (Dr. H Glenn), 117
Micro-electrode for Electro-physiological Work (J. Worst), 749
Microflora of Central African Soils · Temperature Characteristics of the (H. Laudelout and J Meyer), 791
Micro-method for the Examination of the Biochemical Activities of Micro-organisms (J. Dingle and G. L. Solomons), 425
Micronesian Atoll : Material Culture of a, 770
Micro-organisms : Chemistry of the Oxidative Metabolism of certain Aromatic Compounds by (Dr. W. Charles Evans, B. S. W. Smith, Prof. R. P. Linstead and Dr. J. A. Elvidge), 772
  Effect of Cold on (Society for Applied Bacteriology Symposium on), 990
  Effect of Oxidized *d*-Limonene on (I. Zukerman), 517
  A Micro-method for the Examination of the Biochemical Activities of (J. Dingle and G. L. Solomons), 425
Micro-radiography of Biological Specimens X-Ray (Dr. W. Ehrenberg and W. E. Spear), 513

Micro-radiography and Diffraction Investigations : Intense Gallium X-Rays for (A. Taylor), 471
Microscope : How Industry is Using the (Royal Microscopical Society Exhibition), 814
  Society under the, *review* by Prof. T. H. Marshall, 847
  X-Ray Shadow (Dr. V. E. Cosslett and W. C. Nixon), 24
Microscopy : Industrial, 814
Microspheres of Organic Substances (G. A. H. Elton), 1127
Microwave Frequencies: Dielectric Behaviour of Human Blood at (Dr. H. F. Cook), 247
Middle East : The, a Physical, Social and Regional Geography (Dr. W. B. Fisher), *review* by R. N. R. B., 928
Migration : Vertical, of Plankton Animals (Prof. A. C. Hardy and R. Bainbridge), 327
Mildew-preventing Activity of Rhodanine Derivatives (Frances C. Brown and Dr. Charles K. Bradsher), 171
Military Strategy : Geology and (Prof. W. B. R. King), 226
Mind : Liberties of the (Charles Morgan), 306
Mind and Matter : Measurements of (Dr. G. W. Scott Blair), *review* by G. R. Noakes, 136
Mineral Resources in the British Colonies : Geology and (Prof. R. C. Dunham), 1109
Mineralogy (Optical) : Elements of (Prof. Alexander N. Winchell, with collaboration of Prof. Horace Winchell), fourth edition, Part 2, *review*, 311
Minerals : Odours of (Dr. W. McCartney), 274
Minerals and Magmas—Studies at High Temperatures and Pressures (E. D. Lacy), 537
Mining : Physiological Problems of (British Association, Section I (Physiology), Discussion on), 642
Mixing and Agitating in Liquid Media (Institution of Chemical Engineers Conference on), 376
Molasses and other Beet-sugar Industry By-products : Chromatographic Analysis of Amino-acids of (Eugenio Mariani and Giorgio Torraca), 959
Molecular Dynamics and Chemicals Problems (Dr. H. W. Thompson), 369
Molecular Weight of Actinomycin from *Streptomyces* S-67 : Radiocrystallographic Study and (H. Sarlet, J. Toussaint and H. Brasseur), 469
Molecules : Quantum Theory of, *review* by Prof. M. J. S. Dewar, 970
  Structure of, and the Chemical Bond (Y. K. Syrkin and M. E. Dyatkina), translated and revised by M. A. Partridge and D. O. Jordan, *review* by Prof. M. J. S. Dewar, 970
Molecules (Organic) : Theoretical Determination of Electron Density in (Dr. O. Klement), 162 ; (Prof. C. A. Coulson, P. W. Higgs and N. H. March), 1039
Molécules géantes . Etat actuel de la chimie et de la physique des (Prof. H. Mark, avec la collaboration de Prof. T. Alfrey et Prof. R. B. Mesrobian), *review* by Dr. D. P. Riley, 355
Moles and Insectivorous Moles (Rodent) : Adaptation in, and the Theory of Convergence (Dr. G. Eloff), 1001
Molybdenum : Radiochemical Determination of Chromium, Vanadium and, by means of Radioactive Silver (Dr. J. Govaerts and Carlos Barcia-Goyanes), 198
Monolayers of Synthetic Protein Analogues (Toshizo Isemura, Kozo Hamaguchi, Dr. Hisaya Tani, Junzo Noguchi and Heimei Yuki), 165
Montefiore Prizes for Electrical Development, 413
Moon: Blue Sun and (Dr. William Paul and Prof. R. V. Jones), 545, 554 ; (R. R. Wilson), 545 ; (G. F. Lothian), 1086
Morphogenesis : *Marsilea* spp.—Materials for the Experimental Study of (A. Allsopp), 301
Mosquito New to Great Britain : *Culex* (*Culex*) *torrentium* Martini, a (P. F. Mattingly), 172
Mosquitoes in Malaya : Effects of DDT upon Different Species of (J. A. Reid), 863
Mothproofing (R. W. Moncrieff), *review*, 263
Mould Lipase—Effect of Addition of Vitamins and Sterol to the Cake Medium on the Growth and the Activity of the Lipolytic Mould (Dr. C. V. Ramakrishnan and Prof. B. N. Banerjee), 917
Moulds : Apyrases of (P. S. Krishnan), 171
Moulting Hormone in *Rhodnius* : Source of (Dr. V. B. Wigglesworth), 558
Mountains of New Guinea : Old (L. Evelyn Cheesman), 597
Mouse : Effect of Irradiation by X-Rays on the Exhalation of Carbon Dioxide by the (Prof. G. Hevesy and A. Forssberg), 692
Mouse (House) : A Pronounced Sex Difference in Recombination Values in the Sixth Chromosome of the (S. A. Mallyon), 118
Mouse Eggs : Transplantation of (R. A. Beatty), 995
Mouse Embryo Mince : Differentiation of Skeletal Structures from, in the Peritoneum of Adult Mice (Theodore S. Hauschka), 1130
Mouse Epidermis : Deoxyribosenucleic Acid Synthesis during Cell Division in the (Dr. W. S. Bullough and Dr. J. Pasteels), 608
Multiple-Beam Interference Fringes : Superposition Effects in (Audrey M. Glauert), 861
Muscle : The 'Lotmar–Picken' X-Ray Diffraction Diagram of (Prof. Richard S. Bear and Dr. Cicely M. M. Cannan), 684
Muscle (Dried) : The Lotmar–Picken X-Ray Diagram of (Dr. C. H. Bamford and W. E. Hanby), 1085
Muscle (Unstriated) : Active Relaxation of, produced by Adrenaline (Sunita Inderjit Singh and Prof. Inderjit Singh), 829
Muscle (Human Fat and) : Thermal Conductivity of (Dr. H. Stafford Hatfield and Dr. L. G. C. Pugh), 918
Muscle Fibre Membrane : Nature of the Striated (A. Conte and Dr. P. Rieser), 695
Muscle Tissue Constituents: Paper Chromatography of—Paper Chromatography of Adenosine Phosphates (Dr. Olle Snellman and Dr. Bertil Gelotte), 461 ; A Phosphate-absorbing Protein from Muscular Tissue (Dr. Bertil Gelotte), 461 ; The Prosthetic Group of Actin (Dr. Olle Snellman and Dr. Bertil Gelotte), 462
Muscular Contraction : Dephosphorylation of Adenosine Triphosphate in (W. F. H. M. Mommaerts and Joseph C. Rupp), 957
Museum Displays : Representation of Snow in (W. T. Starling), 145
Mushrooms : Eelworms (Nematodes) as Pests of (Charles A. Thomas and George H. Mitchell), 274
Mutation in a Bacterial Virus (Brigadier J. S. K. Boyd), 994
Mutations : Genes and (Cold Spring Harbor Symposium on), 732
Mycobacterium (Pathogenic) : A New Type of (Dr. A. Nordén and Dr. F. Linell), 826
Mycology : Lectotypes in, a Taxonomic Proposal (E. J. H. Corner), 1031
Mycology over a Century (Prof. W. Brown), 231
Mycology and Bacteriology : Applied (L. D. Galloway and Dr. R. Burgess), third edition, revised by L. G. Galloway, *review* by Dr. John Grainger, 7
Mycopathologia et Mycologia Applicata, Vol. 5, Fasc. 1, 62
Mygalomorph Spider in Samoa (Prof. B. J. Marples), 300
Myotatic Reflex Arc : Afferent Limb of the (Dr. A. K. McIntyre), 168
Myrothecium verrucaria : Purification of the Cellulase of (D. R. Whitaker), 1070
Mysidacea : The British (the late Prof. W. M. Tattersall and Olive S. Tattersall), *review* by Dr. W. T. Calman, 924
Mythical Little People of Oceania : The Menehune of Polynesia and other (Katharine Luomala), 639
Mytilicola intestinalis, Steuer, in the European Flat Oyster (*Ostrea edulis*), (R. H. Baird, G. C. Bolster and Dr. H. A. Cole), 560
Myxobacteria Mistaken for Nitrifying Bacteria (Joyce B. Grace), 117 ; (Dr. Jane Meiklejohn), 561

NALARAYADAVADANTICARITA : The (Adventures of King Nala and Devadanti), (edited and translated by Ernest Bender), 939
Namengebung in der Antarktis : Zur Frage der (Dr. J. Georgi), 275
Nasturtium officinale : The So-called Chromosome Races of *Cardamine pratensis* and (Dr. H. W. Howard), 477 ; (Dr. G. Haskell), 478
National Administration and International Organization, a Comparative Survey of Fourteen Countries (International Institute of Administrative Sciences and Unesco), 797
National Boundaries : Movements of Books across, 437
National Polish Science Congress : First (Dr. J. Needham), 241
National Radio Exhibition, 146
Nationalized Industry : The Men on the Boards, a Study of the Composition of the Boards of (Acton Society Trust), 130
Natural History—Birds and Mammals (David Seth-Smith), *review* by M. A. C. Hinton, 136
Natural History of Man in Britain (Prof. H. J. Fleure), *review* by M. C. Burkitt, 757
Natural Products of India, *review* by Sir John Simonsen, 618
Natural Resources : Conservation of (edited by Guy-Harold Smith), *review* by Prof. L. Dudley Stamp, 485
Natural Resources of Canada—Annual Departmental Report for 1948–49, 544
Natural Science and the Spiritual Life (Rev. John Baillie), *review* by the Very Rev. Dr. W. R. Matthews, 968
Natural and Artificial Production of Atmospheric Precipitation (British Association, Section A (Mathematics and Physics), Discussion on), 533
Naturalist in the Gran Chaco (Sir John Graham Kerr), *review* by Prof. James Ritchie, 260
Nature : Modern Insecticides and the Balance of (Dr. D. Stewart MacLagan), 360
Nature Through the Year (Frances Pitt), *review* by T. H. Hawkins, 6
Nature Conservation : International, 175
Nature Reserve in Ross and Cromarty, 938
Nature Study : A Popular, *review* by T. H. Hawkins, 6
Naturwissenschaftliche Illustration : Die (Claus Nissen), *review* by F. J. C., 486
Navigators : Ancient Polynesians as, 499
Néel Point : Anomalous Variation of Young's Modulus of Antiferromagnetics at the (Dr. R. Street and B. Lewis), 1036
Negative Point-to-Plane Corona—a New Mode of Discharge (Allan Greenwood), 41
Nelumbo Fruits : Longevity of, 905
Nematodes : Free-Living, *review* by Prof. C. H. O'Donoghue, 801
  Soil and Freshwater (Dr. T. Goodey), *review* by Prof. C. H. O'Donoghue, 801
Nematodirus in Sheep : A New Species of (Dr. H. D. Crofton and R. J. Thomas), 559
Neo-Vitalism and Farming, *review* by Sir John Russell, 926
Neon–Oxygen Mixtures : Atmospheric Oxygen Bands in Emission from, and in Night Sky and Auroral Luminescences (G. Kvifte), 741
Nerve-Muscle Preparation (Mammalian) : The Rabbit Lumbrical, a New Isolated (D. J. Jenden, K. Kamijo and D. B. Taylor), 880
Nervous System : Corpora amylacea in the Central (J. Molnar), 39
  The Electrical Activity of the (Dr. Mary A. B. Brazier), *review*, 972
Neurospora crassa : Transaminases in (Dr. J. R. S. Fincham), 957
Neurotropic Variant of Influenza Virus : Protection by Receptor-destroying Enzyme against Infection with a (H. J. F. Cairns), 335
Neutral Characters in Evolution : Non-adaptive or (Dr. A. J. Cain), 1049 ; (Dr. G. S. Carter), 1049
  So-called Non-Adaptive or (Dr. A. J. Cain), 424
Neutrons (Cold) : Inelastic Scattering of (P. A. Egelstaff), 290
New Guinea : Old Mountains of (L. Evelyn Cheesman), 597
New Zealand : Blood Parasites of Mammals in (Dr. M. Laird), 640
  Earthquake Activity in, during 1949, 1067
Newt Embryo : Antigens in the Developing (R. M. Clayton), 120
Newton (Sir Isaac) Exhibition at the Royal Society, 189
Nickel Catalysts : Activated Adsorption of Hydrogen on (Dr. G. C. A. Schuit and N. H. de Boer), 1040
Nicotinic Acid Derivatives : Paper Chromatography of (Dr. E. Kodicek and K. K. Reddi), 475
Nimrod Digital Computer : Faster than Thought—the Ferranti (Ferranti, Ltd.), 70
Nitrifying Bacteria : Myxobacteria Mistaken for (Joyce B. Grace), 117 ; (Dr. Jane Meiklejohn), 561
Nitrile-Diene and *n*-Heptane Cyclizations : Activity of the Chromium–Aluminium Oxide Catalyst System in the (Dr. G. J. Janz and P. J. Hawkins), 387
Nitrite Ion : Dimensions of the (Mrs. M. R. Truter), 344
Nitrogen : Spectra of Flames burning with Oxides of (B. B. Fogarty and H. G. Wolfhard), 1122
Nitrogen-fixing Blue-Green Algae : Effect of, on the Growth of Rice Plants (Dr. A. Watanabe, S. Nishigaki and C. Konishi), 748
Nitrogen-15-labelled Nitrogen Mustard : Combination of, with Proteins (Dr. V. C. E. Burnop, Miss D. E. Richards, Dr. W. M. Watkins and Prof. A. Wormall), 251

Nitrogen Compounds (Extra-cellular) : Formation of, by Fungi (A. G. Morton), 333
'Nitrogen Mustard' : Degradation of Deoxyribonucleic Acid by a (Dr. J. A. V. Butler, L. Gilbert, D. W. F. James and W. C. J. Ross), 985
Nitrogen Mustard (Nitrogen-15-labelled) : Combination of, with Proteins (Dr. V. C. E. Burnop, Miss D. E. Richards, Dr. W. H. Watkins and Prof. A. Wormall), 251
Nitrogen Nutrition of Clover (J. T. Vantsis and Dr. G. Bond), 339
$NiOFe_2O_3$ at Low Temperature · Ferromagnetic Resonance Absorption and a New Transition in (Prof. Toshihiko Okamura), 162
Nitroparaffins : New Derivatives of, and their Antitubercular and Antirickettsial Properties (Prof. T. Urbanski), 562 ; *erratum*, 984
Nobel Prize for Chemistry for 1951 awarded jointly to Prof. E. M. McMillan and Prof. G. T. Seaborg, 897
Nobel Prize for Medicine for 1951 awarded to Dr. Max Theiler, 768
Nobel Prize for Physics for 1951 awarded jointly to Sir John Cockcroft and Prof. E. T. S. Walton, 897
Nodule Organism in the Field · Multiple Infection of Clover Plants by Strains of the (Kathleen J. Baird), 116
Nombres transfinis : Leçons sur les (Prof. Wacław Sierpinski), nouveau tirage, *review*, 758
Non-adaptive Characters in Evolution (Dr. G. S. Carter), 700
Non-adaptive or Neutral Characters in Evolution (Dr. A. J. Cain), 1049 ; (Dr. G. S. Carter), 1049
Non-adaptive or Neutral Characters in Evolution So-called (Dr. A. J. Cain), 424
Non-nucleated Halves of *Acetabularia mediterranea* studied with Carbon-14 Dioxide · Protein Synthesis in Nucleated and (Prof. J. Brachet and Dr. H. Chantrenne), 950
nor-Adrenaline on Paper Chromatograms : A Colour Reaction distinguishing between Adrenaline and (Dr. A. J. Glazko and W. A. Dill), 32
Norway Spruce : Cambial Injuries in a Pruned Stand of (W. R. Day), 412
Nuclear Alignment : An Experiment on—the Anisotropy of γ-Radiation from Oriented Cobalt-60 Nuclei (J. M. Daniels, Dr. M. A. Grace and F. N. H. Robinson), 780
Nuclear Disintegrations caused by Fast Cosmic-Ray Neutrons in Photographic Emulsions (Dr. J. Pernegr), 1005
Nuclear Emulsions : Measurements of Mass Ratios in (Prof. Sten von Friesen and Krister Kristiansson), 377
Nuclear Reaction Radiography (Mats Hillert), 39
Nuclear Research Emulsions for Fast-Neutron Dosimetry : Use of (Dr. H. A. B. Simons), 835
Nuclear Science and Engineering : Electronics in (Dr. Denis Taylor), 948
Nuclear Spin of Rubidium-86 (E. H. Bellamy), 556
Nuclear Technology : Industrial and Safety Problems in (edited by Prof. Morris H. Shamos and Prof. Sidney G. Roth), *review* by Sir John Cockcroft, 263
Nucleated and Non-nucleated Halves of *Acetabularia mediterranea* studied with Carbon-14 Dioxide : Protein Synthesis in (Prof. J. Brachet and Dr. H. Chantrenne), 950
Nucleation (Division of Industrial and Engineering Chemistry of the American Chemical Society eighteenth Christmas Chemical Engineering Symposium), 500
Nuclei from Plant Cells : Isolation of (Dr. R. Brown), 941
Nucleic Acid : An Electron Microscope Study of (S. T. Bayley), 470
Nucleic Acid Components : A Rapid Method for the Determination of, by Paper Partition Chromatography (Jan-Erik Edström), 876
Nucleic Acid Constituents : Effect of certain, on the Growth of some Higher Fungi (Dr. Nils Fries), 1045
Nucleic Acids : The Biochemistry of the (Prof. J. N. Davidson), *review*, 52
Nucleic Acids (Bacterial) : Localization of, and Mechanism of the Gram Reaction (Helmer Hoffman), 464
Nucleic Acids in the Liver : Effect of Vitamin B_{12} on the Synthesis of Protein and (M. R. Sahasrabudhe and M. V. Lakshminarayan Rao), 605
Nucleons (High-Energy) : Experiments on the, and Quanta (Sir John Cockcroft), 1060
Nucleotide Shock : Kidney Citrate Levels in (C. J. Threlfall, H. B. Stoner and Prof. H. N. Green), 297
Nucleus : The Chemistry and Physiology of the (Brookhaven National Laboratory Conference on), 189
Numbers : Large Prime (Dr. J. C. P. Miller and D. J. Wheeler), 838
Nutrition . A Philosophy of (Dr. Francis Aylward), 1100

OAK in Great Britain : General Volume Table for (F. C. Hummel and W. T. Waters), 111
Oat Seedlings : A Technique for taking Successive Shadowgraphs of (Dr. O. V. S. Heath), 950
Oberflächenwellen : Über die Bestimmung des Azimuts von Fernbeben aus (Prof. W. Hiller), 1106
Observations : Runs in a Sequence of (Prof. P. V. Krishna Iyer and A. S. Prakash Rao), 557 ; *erratum*, 770
Ocean Floor : Density of Bottom Animals on the (Prof. R. Spärck), 112
Oceania : The Menehune of Polynesia and other Mythical Little People of (Katharine Luomala), 639
Oceanographic and Climatic Conditions in the Sea as exemplified by the English Channel : Influences of Tidal Streams on (Dr. G. Dietrich), 8
Oceanography : Research in (L. H. N. Cooper), 184
Octadecan-1 : 18-diol from Spanish Broom : Isolation of (Dr. O. C. Musgrave, James Stark and Prof. F. S. Spring), 298
Ocular Scanning and Depth Perception (J. Adamson), 345
Odostomia attacking Oysters (Dr. H. A. Cole), 953
Odours of Minerals (Dr. W. McCartney), 274
Oersted Medal of the American Association of Physics Teachers presented to Prof. J. W. Hornbeck, 156
Œstrogens in Urine : Fluorometric Determination of Natural—Elimination of Fluorogenic Compounds (Michael Finkelstein), 830
Oil Palm of West Africa : Unusual Features of the Root System of the (J. O. Wright), 748
Oils : The Essential (Dr. Ernest Guenther), Vol. 4, *review* by Dr. E. G. Kellett, 395
    Vegetable (British Standard 628–32 : 1950 and 650–56 : 1950), 103
Oils and Fats : Methods of Analysis of (British Standard 684 : 1950), 103
Olefins : Course of the Oxidation of, by Chromic Acid (Dr. W. J. Hickinbottom and D. G. M. Wood), 33
Olfactory Enzymes in the Rabbit : Localization of Gustatory and, and the Problems of Taste and Smell (A. F. Baradi and Dr. G. H. Bourne), 977
Operational Calculus based on the Two-Sided Laplace Integral (Dr. Balth van der Pol and Dr. H. Bremmer), *review* by J. H. Pearce, 133
Operators : Functional (John von Neumann), Vol. 1, *review*, 717
'Opossum Shrimps', *review* by Dr. W. T. Calman, 924
Optical Engineering . Sir Charles Parsons and (F. Twyman), 189, 638
Optical Forms of Tris-Acetylacetone Cobalt III : Preparation of the (Dr. F. P. Dwyer and Miss E. C. Gyarfas), 29
Optical Interference : Fourier Synthesis by (A. W. Hanson, C. A. Taylor and Dr. H. Lipson), 160
Optical Rotation and Chain Folding in Synthetic Polypeptides and Gelatin (Dr. Conmar Robinson and M. J. Bott), 325
Optical Systems · A Discharge Illuminant for, capable of either Continuous or Flash Operation (E. J. G. Beeson and A. A. Webb), 1038
Optically Active Compounds : Determination of the Absolute Configuration of, by means of X-Rays (Prof. J. M. Bijvoet, A. F. Peerdeman and A. J. van Bommel), 271
Optics (Electron) : Introduction to (Dr. V. E. Cosslett), second edition, *review*, 803
Orange Oil : The Fermentation-inhibiting Properties of (D. A. A. Mossel), 999
Orchids : British, *review* by Prof. J. W. Heslop Harrison, 353
    Wild, of Britain (V. S. Summerhayes), *review* by Prof. J. W. Heslop Harrison, 353
l'Organe voméro-nasal : Ouvrages sur (Louis Jacobson), *review* by Prof. F. J. Cole, 529
Organic Acids of the Apple Fruit (A. C. Hulme and Dr. T. Swain), 254
Organic Bases . Paper Partition Chromatography of some, by the method of N-Methylation (Tetsuo Kariyone and Dr. Yohei Hashimoto), 739
Organic Design (Dr. C. F. A. Pantin), 227
Organic Substances : Microspheres of (G. A. H. Elton), 1127
Organic Syntheses (edited by Arthur C. Cope), Vol. 30, 1950, *review* by Prof. John Read, 928
Organisms (Small) : Undulatory Propulsion in (Prof. J. Gray), 929
Organo-Iron Compound : A New Type of (T. J. Kealy and Dr. P. L. Pauson), 1039
Orientation : Effect of, on the Metallic Reflexion of Polarized Light (D. H. Woodard and E. L. Bronson), 742
Orkney (Hugh Marwick), *review*, 803
Ornithological Pioneer : An, *review* by Dr. A. Landsborough Thomson, 216
Oscillations (Nonlinear) : Contributions to the Theory of (S. P. Diliberto, L. L. Rauch, F. H. Brownell, M. L. Cartwright, J. G. Wendel, C. E. Langenhop, A. B. Farnell, W. Wasow, edited by S. Lefschetz), *review* by Prof. H. T. H. Piaggio, 49
Osmium Tetroxide : Perhydroxylation of Indole Derivatives by (D. W. Ockenden and Dr. K. Schofield), 603
Osmond (Grande Médaille) of the Société Française de Métallurgie presented to Prof. E. N. da C. Andrade, 768
Ostrea edulis · *Mytilicola intestinalis*, Steuer, in the European Flat Oyster (R. H. Baird, G. C. Bolster and Dr. H. A. Cole), 560
Ottawa : The Cosmic Ray Observatory at (Dr. D. C. Rose), 269
Ovalene : Electrical Conductivity and Magnetic Susceptibility of (Prof. Hideo Akamatu, Hiroo Inokuchi and Takashi Handa), 520
Ovarian Dermoid Cyst Fat : Nature of (Dr. V. R. Wheatley), 1128
Ox Ligament : Elastin from Human Tissue and from (Dr. David A. Hall), 513
Oxford Atlas : The (edited by Brigadier Sir Clinton Lewis and Colonel J. D. Campbell), *review*, 1016
Oxidation : Dry, and Wet Corrosion (Dr. U. R. Evans), 853
Oxidation of Benzaldehyde : Mechanisms of (M. F. R. Mulcahy and I. C. Watt), 123
Oxidation of Glucose : Reversible, by Glucose Dehydrogenase (Prof. Harold J. Strecker and Dr. Seymour Korkes), 913
Oxidation of Glucose by *Aerobacter* sp. : Direct (Dr. J. De Ley and S. Cornut), 515
Oxidation of Glucosides to Glucuronides : Catalytic (C. A. Marsh), 602
Oxidation of Hexane · Inert Gas Effects in the (N. J. H. Small and Prof. A. R. Ubbelohde), 201
Oxidation of Olefins by Chromic Acid : Course of the (Dr. W. J. Hickinbottom and D. G. M. Wood), 33
Oxides of Nitrogen : Spectra of Flames burning with (B. B. Fogarty and H. G. Wolfhard), 1122
Oxy-Acids : Properties and Reactions of Mixtures of Trifluoroacetic Anhydride and (Dr. E. J. Bourne, Dr. J. E. B. Randles, Dr. J. C. Tatlow and Dr. J. M. Tedder), 942
Oxygen Affinities of Respiratory Blood Pigments in *Serpula* (Prof. H. Munro Fox), 112
Oxygen Bands : Atmospheric, in Emission from Neon–Oxygen Mixtures, and in Night Sky and Auroral Luminescences (G. Kvifte), 741
Oxygen Uptake of Nucleated and Non-nucleated Halves of *Amoeba proteus* (Prof. J. Brachet), 205
Oxygen and Carbon Isotopes in Carbonate Rocks : Relative Abundances of (Dr. P. Baertschi), 288
Oyster (*Ostrea edulis*) (European Flat) : *Mytilicola intestinalis*, Steuer, in the (R. H. Baird, G. C. Bolster and Dr. H. A. Cole), 560
Oysters : An *Odostomia* attacking (Dr. H. A. Cole), 953

PACIFIC : Filariasis in the (Sir Philip Manson-Bahr), 776
Paint Film Defects (Manfred Hess), *review* by Dr. A. E. A. Werner, 715
Paints . Technology of Defects in, *review* by Dr. A. E. A. Werner, 715
Palæontological Documentation and Translation Service : French, 857
Palæontology and Evolution : Vertebrate (British Association, Sections C (Geology) and D (Zoology), Discussion on), 583
Palatability of Birds' Eggs (Dr. Hugh Cott), 1110
'Paludrine' · A Metabolite of, with High Antimalarial Activity (Dr. H. C. Carrington, Dr. A. F. Crowther, Dr. D. G. Davey, Dr. A. A. Levi and Dr. F. L. Rose), 1080
Pancreas of the Dog and Parotid of the Pig : Cholinesterase Activity in the Secretions of the (Prof. R. A. McCance, L. M. Brown, Dr. R. S. Comline and D. A. Titchen), 788
Paper : A New Method for the Detection of Amino-Acids, Peptides, Proteins and other Buffering Substances on (Dr. J. Porath and P. Flodin), 202

Parallax (Annual) : An Attempt to Measure the, or Proper Motion of Four Radio Stars (F. G. Smith), 962
Parasite *Bracon gelechiae* Ashmead (Braconidae) : Effect of Hosts on the Egg Coloration of the (G. C. Sen Gupta), 793
Parasitology : Future of, 327
Parathion *in vivo* : Cholinesterase Inhibition by (W. M. Diggle and J. C. Gage), 998
Parents : Is Age of, Important in Sheep ? (R. A. Barton), 37
Parotid of the Pig : Cholinesterase Activity in the Secretions of the Pancreas of the Dog and (Prof. R. A. McCance, L. M. Brown, Dr. R. S. Comline and D. A. Titchen), 788
Parsons Memorial Lecture for 1951 of the Physical Society (F. Twyman), 189, 638
Particle Size : Relationship between the Extinction Coefficient and the (Dr. Horace E. Rose), 784
Partridge (Dr. Norman) Memorial Award of the British Institution of Radio Engineers awarded to S. W. Punnett, 413
Past : Dating the (Prof. Frederick E. Zeuner), second edition, *review* by Dr. E. C. Bullard, 48
Pasture Crops : Forage and (W. A. Wheeler), *review* by J. O. Green, 575
Patenting of Inventions : Introduction to the (Cecil Hollins), *review* by R. G. Lloyd, 973
Pathogenic *Mycobacterium* : A New Type of (Dr. A. Nordén and Dr. F. Linell), 826
Pea Juice : Penicillin Formation in (Dr. R. P. Cook and Dr. Margaret B. Brown), 63
Peat Marl, Caliche and Archæological Materials : Radiocarbon Datability of (H. H. Bartlett), 725
Pectate Gel : Action of Phytopathogenic Bacteria on (Dr. K. A Sabet and Dr. W. J. Dowson), 605
Penetrameters (Industrial Radiology Group of the Institute of Physics Symposium on), 989
Penicillia : A Manual of the (Kenneth B. Raper and Charles Thom), *review* by G. Smith, 261
Penicillin Formation in Pea Juice (Dr. R. P. Cook and Dr. Margaret B. Brown), 63
Penicillin G Solutions : Light-scattering Studies on (C. S. Hocking), 423
Penicillium : Taxonomy of, *review* by G. Smith, 261
Penicillium chrysogenum : Production of Ketoglutarate by (D. J. D. Hockenhull, G. D. Wilkin and F. G. Winder), 1043
Pennsylvania : Instructional Film Research in (C. Denis Pegge), 775
Pentose Nucleic Acids : Separation of Deoxypentose and (Dr. Stephen Zamenhof and Prof. Erwin Chargaff), 604
People at Work (Sixth Present Question Conference), 986
Peptides : Identification of the Free Carboxyl Groups in (J. Tibbs), 910
Peptides, Proteins and other Buffering Substances on Paper : A New Method for the Detection of Amino-Acids, (Dr. J. Porath and P. Flodin), 202
Perhydroxylation of Indole Derivatives by Osmium Tetroxide (D. W. Ockenden and Dr. K. Schofield), 603
Periodate : Decomposition of Formic Acid by (Dr. P. B. Sarkar), 122
Periodicals : The Subject Index to, 1949 (Library Association), *review*, 486
Peritoneum of Adult Mice : Differentiation of Skeletal Structures from Mouse Embryo Mince in the (Theodore S. Hauschka), 1130
Personnel Department in an Industrial Undertaking : Functions of a (G. R. Moxon), 823
Personnel Management, 63, 823
'Perspex' (Coloured) : Light Filters of (Prof. E. J. King and S. Ventura), 702
Pests of Flowers and Shrubs (G. Fox Wilson), second edition, 321
Petalostyles labicheoides : Isolation of Tetrahydroharman from (Dr. G. M. Badger and A. F. Beecham), 517
Petroleum Congress : Third World, 190
Petroleum Consumption and Production in Great Britain (Petroleum Information Bureau Pamphlet on), 412
Pflanzen (höheren) : Grundlagen und Methoden einer Erneuerung der Systematik der (Dr. Franz Buxbaum), *review* by Dr. W. B. Turrill, 1096
*p*H : Effect of Phosphates and the, on Sugar Absorption (Prof. F. Ponz and J Larralde), 912
Pharmacopeia of the United States of America (the United States Pharmacopeia), fourteenth revision (U.S.P. 14) and the first U.S.P. 14 Supplement, *review* by J. H. G., 577
Pharmacy : Practice of (Remington's), tenth edition by Dr. E. Fullerton Cook and Dr. Eric W. Martin, *review* by J. H. G., 1056
Phase-Contrast Refractometer for Liquids and Gases : A Highly Sensitive (Erik Ingelstam), 960
Phenanthrolines : *In vitro* Fungistatic Action of, against Pathogenic Fungi (Dr. F. Blank), 516
Phenolases in the Echinoid, *Diadema antillarum* Philippi (Prof. N. Millott and P. W. Jacobson), 878
Phenolharze : Chemie der (Dr. K. Hultzsch), *review* by N. J. L. Megson, 215
Phenolic Hydroxyl Group in the Human Body : Methylation of a (Prof. N. F. Maclagan and Dr. J. H. Wilkinson), 251
Phenolic Resins : Chemistry of, *review* by N. J. L. Megson, 215
Phenols (Di- and Tri-hydroxy) : Colour Reagents for the Paper Chromatography of (D. G. Roux), 1041
Philippine Trench and its Bottom Fauna (Dr. Anton Fr. Bruun), 692
Philosopher's Physics : A, *review* by F. I. G. Rawlins, 215
Philosophy : The Christian Challenge to (the late W. H. V. Reade), *review* by F. I. G. Rawlins, 178
Philosophy of Nutrition (Dr. Francis Aylward), 1100
Philosophy of Physics, 1850–1950 (Prof. H. Dingle), 630
Phosphatase Activity of the Liver of the Rat (Alkaline and Acid) : Effects of a Protein-free Diet on the (J. O. Ely and M. H. Ross), 323
Phosphatase -Positive and -Negative Cell Islets in the Adrenal Medulla of the Rat (Acid) : Histochemical Evidence of the Presence of (Dr. O. Eranko), 250
Phosphate in Acid Soils : Relationship between Base Saturation and Crop Response to (Dr. H. F. Birch), 388
Phosphate Ester of a Tricarboxylic Acid in Liver (S. Rapoport and Robert H. Wagner), 295
Phosphates and the *p*H : Effect of, on Sugar Absorption (Prof. F. Ponz and J. Larralde), 912
Phosphomolybdate : Ultra-violet Absorption of Reduced (Dr. R. Consden and Winifred M. Stanier), 298
Phosphorus (Radioactive) : A Particulate Impurity found in Solutions of (Dr. J. E. Hotchin), 200
Phosphorus Trifluoride-Hæmoglobin (Geoffrey Wilkinson), 514
Photo-conductive Effect in Tellurium Film (W. T. Blackband), 704
Photoelectric Cells : Properties and Uses of, 499
Photo-Flash Tubes : High-Power (Prof. M. Laporte), 552
Photographic Emulsions : Density of Tracks of Protons and Mesons in (Torsten Gustafson), 377
    Nuclear Disintegrations caused by Fast Cosmic-Ray Neutrons in (Dr. J. Pernegr), 1005
Photographie : Wissenschaftliche (Prof. Dr. E. v. Angerer), vierte Auflage, *review* by L. V. Chilton, 485
Photography : Scientific, *review* by L. V. Chilton, 485
Photography in Astronomy (Dr. E. W. H. Selwyn), *review* by L. V. Chilton, 485
Photo-inactivation of the Plant Hormone Indoleacetic Acid by Fluorescent Substances (Dr. Mario G. Ferri), 334
Photosynthesizing Cells : Transfer of Light Energy within the Pigment Systems present in (L. N. M Duysens), 548
Phycologists at Bangor : Meeting of, 639
Physical Aspects of Organic Chemistry (Dr. William A. Waters), fourth edition, *review* by Dr. J. W. Baker, 92
Physical Adsorption Processes : Influence of a Chemisorbed Film on subsequent (A. S. Joy and T. A. Dorling), 433 ; (P. F. Tiley), 434
Physical Basis of Internal Calorimetry (Dr. W. Chester and Dr. J. Grayson), 521
Physicists (Experimental) : Relativity for, *review* by Prof. H. T. H Piaggio, 353
Physics (S. G. Starling and Dr. A. J. Woodall), *review* by G. R. Noakes, 971
    A Century of, 622
    Essays in (Viscount Samuel), *review* by F. I. G. Rawlins, 215
    Laboratory (J. H. Avery and A. W. K. Ingram), *review* by S. Weintroub, 355
    Low-Temperature (Dr. B. Bleaney and Dr. R. Bowers), 807
    A Philosopher's, *review* by F. I. G. Rawlins, 215
    Philosophy of, 1850–1950 (Prof H. Dingle), 630
    Recent Researches in, *review* by S. Weintroub, 484
    Reports on Progress in, Vol. 13 (1950), (Physical Society), *review* by S. Weintroub, 484
Physics (Metal) : Progress in (edited by Dr. Bruce Chalmers), Vol. 2, *review* by Dr. W. Hume-Rothery, 801
    Recent Developments in, *review* by Dr. W. Hume-Rothery, 801
Physics (Theoretical) : Lectures on, *review* by Prof. R. E. Peierls, 887
Physics in Canada 1951, 1067
Physics at Leeds, 856
Physics at Queen's University, Kingston, Ontario, 60
Physics in the Diagnosis and Treatment of Cancer : Applications of (Physical Society Symposium on), 1023
Physics of Electrical Discharge (Prof. F. Llewellyn Jones), 140
Physics with the Larger Harwell Pile : Some Experimental Work carried out in, 581
Physics of High Pressure (Prof. P. W. Bridgman), new impression with Supplement, *review*, 972
Physics for General Honours Students, *review* by G. R. Noakes, 971
Physics in the Last Fifty Years (Prof. Max Born), 625
Physics from 1850 to 1900 (Prof. E. N. da C. Andrade), 622
Physics as Science and as Art (Dr. K. K. Darrow), 411
Physics of Social Equilibrium (Prof. T. S. Simey), 546, 1049 ; (Dr. R Furth), 1048
Physics Revised : A Classic in, *review* by Prof. W. H. McCrea, 1053
Physics To-day (American Institute of Physics Symposium on), 411
Physik (theoretische) : Vorlesungen über (Prof. Arnold Sommerfeld), Band 1, vierte Auflage, Band 2, Band 3, Band 6, *review* by Prof. R. E. Peierls, 887
Physiological Problems of Mining (British Association, Section I (Physiology), Discussion on), 642
Physiology (Lactational) : Terminology for Use in (Dr. A. T. Cowie, Dr. S. J. Folley, B. A. Cross, Dr. G. W. Harris, Dora Jacobsohn and K. C. Richardson), 421
Physiology of the Capillaries (Prof. H. P. Gilding), 230
Physiology of the Nucleus : The Chemistry and (Brookhaven National Laboratory Conference on), 189
Physique des molécules géantes : Etat actuel de la chimie et de la (Prof. H. Mark, avec la collaboration de Prof. T. Alfrey et Prof. R B. Mesrobian), *review* by Dr. D. P. Riley, 355
Phytomorphology, a New Botanical Journal (International Society of Plant Morphologists), 1067
Phytopathogenic Bacteria : Action of, on Pectate Gel (Dr. K. A. Sabet and Dr. W. J. Dowson), 605
Phytophthora infestans in Kenya : New Hosts of (R. M. Nattrass and Moira Ryan), 85
Phytoplankton : Freshwater, *review* by Prof. F E. Fritsch, 396
Pig : Cholinesterase Activity in the Secretions of the Pancreas of the Dog and Parotid of the (Prof. R. A. McCance, L. M. Brown, Dr. R. S. Comline and D. A Titchen), 788
Pig Fat and Vitamin E Deficiency : A Brown Discoloration of (K. L. Robinson and W. E. Coey), 997
Pigment Systems present in Photosynthesizing Cells : Transfer of Light Energy within the (L. N. M. Duysens), 548
Pigment/Vehicle Relationships (Oil and Colour Chemists' Association Symposium on), 235
Pilchards : Breeding of, off the West Coast of South Africa (Dr. C. Von Bonde and D. H. Davies), 952
    Breeding Ground of, off the Coast of South-West Africa (Dr. T. J. Hart and N. B. Marshall), 272
Pittsburgh Award of the Pittsburgh Section of the American Chemical Society made to Dr. W. A. Gruse, 1104
Planetary Configurations : Unstable (Dr. W. H. Ramsey), 676
Plankton Animals : Vertical Migration of (Prof. A. C. Hardy and R. Bainbridge), 327
Planning : Town and Country, 1943–1951 (Progress Report by the Minister of Local Government and Planning on the Work of the Ministry of Town and Country Planning), 45
Planning the Land of Britain, 967

Planning and Land Utilization, 45
Plant (Fossil): Electron-Microscopic Observations on the Xylem Elements of a (A. Wesley and B. Kuyper), 137
Plant Biochemistry (James Bonner), *review*, 4
Plant Cells: Isolation of Nuclei from (Dr. R. Brown), 941
Plant Embryology (Donald Alexander Johansen), *review* by Prof. R. C. McLean, 619
Plant Hormone Indoleacetic Acid: Photo-inactivation of the, by Fluorescent Substances (Dr. Mario G. Ferri), 334
Plant Industry in Australia, 187
Plant Life: The Synthesis and Functions of Sugars in (Prof. E. L. Hirst), 61
Plant Morphology: A Hundred Years of (Dr. H. Hamshaw Thomas), 312
Plant Pathology (Prof. John Charles Walker), *review* by Dr. S. G. Jones, 93
Plant Viruses: A Biological Approach to (Dr. J. S. Kennedy), 890
Plant and Animal Nutrition in relation to Soil and Climatic Factors (British Commonwealth Scientific Official Conference: Specialist Conference in Agriculture, Australia 1949, Proceedings), 499
Plants: Acid Tolerance in (Prof. W. Neilson Jones and Ida Levisohn), 791
  Marine Animals and, *review* by Dr. N. B. Eales, 1014
Plants (Cultivated): History of (British Association, Section K (Botany), Discussion on), 448
  Origin and Improvement of (M. B. Crane), 376
Plants (Ornamental): Pests of, 321
Plants (Seed): Embryonic Development in the, *review* by Prof. R. C. McLean, 619
Plants and Animals: Trace Elements in (Prof. Walter Stiles), second edition, *review* by K. W., 486
Plasma: Inactivation of Adrenotropic Hormone (ACTH) by (Dr. Max Reiss, F. E. Badrick, I. D. K. Halkerston and C. Plaice), 206
Plasma (Human): Factor *Rh* Activity in (Dr. Ellsworth C. Dougherty), 880
Plasma Clotting: Effect of Shear's Polysaccharide on (Sylvia Most), 342
Plasmin: Quaternary Detergents and the Activity of Trypsin and (Dr. Tage Astrup and Norma Alkjaersig), 565
Plasmodium berghei in Experimentally Infected *Anopheles* spp.: Complete Sporogonic Development of (Dr. M. Yoeli and Miss W. J. Wall), 1078
Plastics: Applications of (H. V. Potter), 328
  Effects of X-Rays upon—Electronic Processes (M. J. Day and Dr. Gabriel Stein), 644; Paramagnetic Processes (Dr. E. E. Schneider, M. J. Day and Dr. Gabriel Stein), 645
Plastics Convention and Exhibition: British, 328
Plastics Industry: Glossary of Terms used in the (British Standard 1755: 1951), 983
Platyctenid Ctenophore from Jamaica: A New (Jessie J. Rankin), 1047
Pneumoconiosis among Coalminers in South Wales: The Social Consequences of (Dr. P. Hugh-Jones and Dr. C. M. Fletcher), 1106
Point-Charge in the Non-symmetric Field Theory (A. Papapetrou and Prof. E. Schrödinger), 40
Polarized Electrons: Detection of Circularly Polarized γ-Rays and the Production of (Prof. Otto Halpern), 782
Polarized Light: Effect of Orientation on the Metallic Reflexion of (D. H. Woodard and E. L. Bronson), 742
Polarographic Conference: Proceedings of the, 19
Polish Science Congress: First National (Dr. J. Needham), 241
Pollen Analysis: Text-Book of Modern (Knut Faegri and Johs. Iversen), *review* by Dr. J. B. Simpson, 309
Polyacetylenic Compounds: Synthesis of (Prof. E. R. H. Jones, Dr. M. C. Whiting, Dr. J. B. Armitage, Dr. C. L. Cook and Dr. N. Entwistle), 900
Polyenes (Deeply Coloured): Catalytic Conversion of a Diene into (B. Eisler and Dr. A. Wassermann, Dr. F. D. Farnsworth, D. Kendrick and Dr. R. Schnurmann), 459
Polyhedral Diffusion Flames (Dr. J. E. Garside and B. Jackson), 1085
Polyisobutylene: Measurements of the Normal Stress Effect in Solutions of (H. W. Greensmith and R. S. Rivlin), 664
Polymerization: Cationic (University College of North Staffordshire Conference on), 545
Polymerization of Acrylonitrile: Ferric-Ion Catalysed Decomposition of Hydrogen Peroxide and the (Dr. Adolf G. Parts), 79
Polymorphism arising from Screw Dislocation (Dr. V. Vand), 783
Polynesia: The Menehune of, and other Mythical Little People of Oceania (Katharine Luomala), 639
Polynesian: The, Master Mariner and Astronomer (T. G. F. Mann), 499
Polynesian Legend: Mythical Dwarf People in, 639
Polynomial Equations: Solution of, with the aid of the Electrolytic Tank (L. Tasny-Tschiassny and A. G. Doe), 702
Polyoxyethylene Ethers (Surface-Active): Antituberculous Effect of certain, in Mice (Dr. J. W. Cornforth, Dr. P. D'Arcy Hart, R. J. W. Rees and J. A. Stock), 150
Polypeptide Chains: Configuration of (Prof. Linus Pauling and Prof. Robert B. Corey), 550
Polypeptides: The 1·5-A. Reflexion from Proteins and (Dr. M. F. Perutz), 653
Polypeptides and Gelatin (Synthetic): Optical Rotation and Chain Folding in (Dr. Conmar Robinson and M. J. Bott), 325
Polypeptides and Proteins (Synthetic): Structure of (Dr. C. H. Bamford and W. E. Hanby), 340
Polyphenoloxidase: Tyrosinase and—the Role of Metallic Ions in Melanogenesis (Dr. Denis Kertész), 697
Polyploidy and the Amounts of Deoxynucleic Acid per Nucleus in the Liver and Kidney of Adult Rats: Relation between (Marion F. Harrison), 248
Polysaccharide (Shear's): Effect of, on Plasma Clotting (Sylvia Most), 342
Polyuronide Hemicellulose (Flax Fibre): Paper Chromatography of (G. C. Whiting), 833
Population Census of England and Wales, 1951 (E. Grebenik), 580
'Positive Particles' near a Source of Radium E: Existence and Nature of the (Dr. F. C. Champion and A. A. Ahmed), 780
Posture: Changes in Colour Sensitivity of the Eye with (Dr. J. N. Aldington), 86; (A. Blackie), 524; (F. Taylor), 524
Potassium-40: Calibration of Geiger–Müller Liquid Counters by the Radioactivity of (Dr. T. A. Chalmers), 870
Potassium Chloride Solutions: Ultrasonic Velocity in, in the Region of their Negative Viscosities (Dr. Satya Prakash, Prem Nath Saxena and Arvind Mohan Srivastava), 522
Potassium Ions in Kidney Slices: Rapid Rate of Turnover of (Dr. R. E. Davies and Dr. A. W. Galston), 700
Potassium Xanthogenates: Paper Partition Chromatography of Alcohols using the (Tatsuo Kariyone, Dr. Yohei Hashimoto and Mutsuo Kimura), 511
Potato: Blight Resistance in (Dr. William Black), 18
Potentiation by Adrenocorticotrophin of the Diabetogenic Action of Growth-Hormone Preparations (Dr. E. Reid), 878
Powder Metallurgy: Science and Technology of, *review* by H. W. Greenwood, 133
  Treatise on (Dr. Claus G. Goetzel), *review* by H. W. Greenwood, 133
Power and Democratic Planning: Freedom, (Dr. Karl Mannheim), *review* by R. Brightman, 844
Power Resources: Fuel and (Appointment by the Minister of Fuel and Power of a Committee to consider the use of), 274
Practitioner: Thousandth Issue of, 681
Pre-Breakdown Discharges in D.C. Positive Point-to-Plane Corona (H. M. Gaunt and Dr. J. D. Craggs), 859
Pregnan-7-ol and Pregnan-12-ol (Dr. W. Klyne), 835
Prehistoric Cave Paintings in South Africa (J. R. Harding), 275
Prehistoric Metallurgy of Copper and Bronze in the Old World: Notes on the (H. H. Coghlan), *review* by M. C. Burkitt, 531
Prehistoric Sites on the North Cornish Coast (Joan R. Harding), 589
Prejudice: The Roots of (Arnold Rose), 862
Present Question Conference on People at Work, 986
Preservation of Biological Materials by Freeze-Drying (Dr. R. J. C. Harris), 851
Pressure (High): The Physics of (Prof. P. W. Bridgman), new impression with Supplement, *review*, 972
Probability and Statistics: Introduction to the Theory of (Prof. Niels Arley and Prof. K. Rander Buch), *review* by David G. Kendall, 217
Processing of Colonial Raw Materials (Charlotte Leubuscher), 1105
Processing Solutions: Chemical Shortages and the Efficient Use of (Scientific and Technical Group of the Royal Photographic Society and the British Kinematograph Society Symposium on), 103
Productivity of British Land (Report of the Rural Reconstruction Association), 187
Productivity of Hot and Cold Deserts: The Biology and (Institute of Biology Conference on), 1068
Profit: Nature of (Prof. R. G. Hawtrey), 228
Proguanil-resistant Laboratory Malarial Strains: A 2:4-Diamino Pyrimidine in the Treatment of (I. M. Rollo), 332
Projectile: Effect of Cross-wind on a (K. Pennycuick), 41
Propagation of Sound Waves in a Ferromagnetic Material: Effect of a Magnetic Field on the (J. de Klerk), 963
Properties of Metallic Materials at Low Temperatures (P. Litherland Teed), review by Prof. F. C. Thompson, 49
Properties of Metals at Elevated Temperatures (George V. Smith), *review* by Prof. F. C. Thompson, 49
Properties and Reactions of Mixtures of Trifluoroacetic Anhydride and Oxy-Acids (Dr. E. J. Bourne, Dr. J. E. B. Randles, Dr. J. C. Tatlow and Dr. J. M. Tedder), 942
Proportional Counter in X-Ray Diffraction Work (A. R. Lang), 907
Propulsion in Small Organisms: Undulatory (Prof. J. Gray), 929
Protective Action of Ethyl Alcohol on Irradiated Mice (Edith Paterson and Joyce J. Matthews), 1126
Protective Action of Methylamine against X-Irradiation (Prof. Z. M. Bacq and A. Herve), 1126
'Protein': Origin of the Word (Sir Harold Hartley), 244
Protein (Low Molecular Weight): Crystal Structure of a—Electron Microscopy of β-Lactoglobulin Crystals (Dr. I. M. Dawson), 241; Structure of Dry β-Lactoglobulin Crystals (Dr. D. P. Riley), 242
Protein Absorption in the New-born Animal: Histological Changes in the Epithelium of the Small Intestine during (Dr. R. S. Comline, H. E. Roberts and D. A. Titchen), 84
Protein Analogues (Synthetic): Monolayers of (Toshiko Isemura, Kozo Hamaguchi, Dr. Hisaya Tani, Junzo Noguchi and Heimei Yuki), 165
Protein Synthesis in Nucleated and Non-nucleated Halves of *Acetabularia mediterranea* studied with Carbon-14 Dioxide (Prof. J. Brachet and Dr. H. Chantrenne), 950
Protein-free Diet: Effects of a, on the Alkaline and Acid Phosphatase Activity of the Liver of the Rat (J. O. Ely and M. H. Ross), 323
Protein–Detergent Complex: Influence of Salt on the Size and Shape of a (J. A. Friend, B. S. Harrap and Dr. J. H. Schulman), 910
Protein and Nucleic Acids in the Liver: Effect of Vitamin B_{12} on the Synthesis of (M. R. Sahasrabudhe and M. V. Lakshminarayan Rao), 605
Proteins: Combination of Nitrogen-15-labelled Nitrogen Mustard with (Dr. V. C. E. Burnop, Miss D. E. Richards, Dr. W. M. Watkins and Prof. A. Wormall), 251
Proteins (Contractile): Alkaline Phosphatase and (Prof. J. F. Danielli), 464
Proteins (Synthetic Polypeptides and): Structure of (Dr. C. H. Bamford and W. E. Hanby), 340
Proteins on Filter Paper: Movement of (Dr. D. A. Hall and Dr. P. Wewalka), 685; (Dr. A. E. Franklin, Prof. J. H. Quastel and Dr. S. F. Van Straten), 687
Proteins and other Buffering Substances on Paper: A New Method for the Detection of Amino-Acids, Peptides, (Dr. J. Porath and P. Flodin), 202
Proteins and Polypeptides: The 1·5-A. Reflexion from (Dr. M. F. Perutz), 653
Proteolytic Activity in Hen's Egg prior to Incubation (Hadar Emanuelsson), 958
Proton–Proton Scattering at 146-MeV. (J. M. Cassels, G. H. Stafford and Dr. T. G. Pickavance), 468
Protons: The Helix as a Linear Accelerator for (D. R. Chick and D. P. R. Petrie), 782
Protons (146-MeV.): Scattering of, by Deuterons (J. M. Cassels, G. H. Stafford and Dr. T. G. Pickavance), 556
Protons and Mesons in Photographic Emulsions: Density of Tracks of (Torsten Gustafson), 377
Pseudo-cholinesterase in the Liver and Serum of Male and Female Rats: Effect of a Single Injection of Carbon Tetrachloride upon the Activity of the (Lucy M. Brown and Marion F. Harrison), 83
Pseudomonas mors-prunorum Wormald: The Leaf Scar as an Avenue of Infection for the Cherry Bacterial Canker Organism (J. E. Crosse), 560

Psyche : Cell and (Edmund W. Sinnott), *review* by Prof. C. H. Waddington, 970
Psychological Research on the Rat : Handbook of (Norman L. Munn), *review* by Alec Rodger, 134
Psychological and Biochemical Effects of Lysergic Acid Diethylamide (Dr. W. Mayer-Gross, Dr. W. McAdam and Dr. J. W. Walker), 827
Psychology : Animal, *review* by Alec Rodger, 134
  Race and (Otto Klineberg), 862
Psychology (General) : Current Trends in (British Association, Section J (Psychology), Discussion on), 866
Psychology (Occupational) : Current Trends in (British Association, Section J (Psychology), Discussion on), 370
Psychology (Social) : Current Trends in (British Association, Section J (Psychology), Discussion on), 593
Psychology and the Laity (Prof. C. A. Mace), 231
Publication : Preparing Technical Material for (University of Illinois Engineering Experiment Station, Circular Series No. 62), 857
Purification of the Cellulase of *Myrothecium verrucaria* (D. R. Whitaker), 1070
Pyrimidine Deoxynucleosides : Application of the Dische Diphenylamine Reaction to (Dr. T. G. Brady and E. McEvoy-Bowe), 299
Pyrogallol Tannins : Paper Chromatography of the (R. S. Asquith), 738
Pyruvate and some other α-Keto-acids : Transamination to (E. V. Rowsell), 104
Pyruvic, Dimethylpyruvic and α-Ketoglutaric Acids in Cultures of *Aspergillus niger* on various Substrates : Chromatographic Detection of (Dr. T. K. Walker, A. N. Hall and J. W. Hopton), 1042

Q-ENZYME : Carbohydrate Primers for (S. A. Barker, A. Bebbington and Dr. E. J. Bourne), 834
Quail in Britain (R. E. Moreau), 1114
Quakers in Science and Industry (Dr. Arthur Raistrick), *review* by V. A. Eyles, 94
Quality in Cacao : Application of an Incomplete Block Design to the Assessment of (J. A. R. MacLean and Robert Wickens), 434
Quanta : Experiments on the High-Energy Nucleons and (Sir John Cockcroft), 1060
Quantum Mechanical Study of Lithium Hydride (Inga Fischer), 1002
Quantum Theory of Molecules, *review* by Prof. M. J. S. Dewar, 970
Quartz Crystals : Applications and Production of, *review* by Dr. W. P. Mason, 1098
Quartz Vibrators and their Applications (Dr. P. Vigoureux and C. F. Booth), *review* by Dr. W. P. Mason, 1098
Quaternary Detergents and the Activity of Trypsin and Plasmin (Dr. Tage Astrup and Norma Alkjaersig), 565
Quaternary Finds in Belgium, 1026
'Quinaldil' : Crystal Structure of (D. R. Davies and H. M. Powell), 386
Quinol : Low-Frequency Dielectric Absorption and Direct-Current Conductivity in (J. S. Dryden and Dr. R. J. Meakins), 1121

RABBIT : Localization of Gustatory and Olfactory Enzymes in the, and the Problems of Taste and Smell (A. F. Baradi and Dr. G. H. Bourne), 977
  Surgically Induced Splenogenic Anaemia in the (Kurt I. Altman, Robert N. Watman and Kurt Salomon), 827
Rabbit Control in Australia—Problems and Possibilities (J. E. Nichols), 930
Rabbit Lumbrical, a New Isolated Mammalian Nerve-Muscle Preparation (D. J. Jenden, K. Kamijo and D. B. Taylor), 880
Rabbit Polymorphonuclear Leucocytes : Ali-esterase of (Miss Esther Wong), 80
Rabbit Semen : The Gelatinous Mass in (Dr. D. P. Mukherjee, M. P. Johari and P. Bhattacharya), 422
Rabbits : Dutch-type White-spotting in (Roy Robinson), 300
  Electric Shock and the Regeneration of the Corneal Epithelium of (Margarete Holzbauer and Prof. R. Rigler), 919
Race and Psychology (Otto Klineberg), 862
Racemization of N-Acylaspartic Acids (Dr. C. C. Barker), 908
Racial Studies (Cedric Dover), 862
Radiation (Ionizing) : A Method of Making Visible the Distribution of Activity in a Source of (Prof. W. V. Mayneord, R. C. Turner, S. P. Newbery and H. J. Hodt), 762
Radiation Therapy : 1,000-Curie Cobalt-60 Units for (Dr. H. E. Johns, L. M. Bates, E. R. Epp, D. V. Cormack, S. O. Fedoruk, A. Morrison, W. R. Dixon and C. Garrett), 1036
Radiative Corrections : Charge-Renormalization accompanying (M. Demeur), 1037
Radicals (Free) : The Reactivity of (Faraday Society General Discussion on), 63
Radio : Awards for Technical Writing on (Radio Industry Council), 858
Radio (Transatlantic) : Anniversary of (Dr. R. L. Smith-Rose), 980
Radio Convention (British Institution of Radio Engineers), 948
Radio Exhibition : National, 146
Radio Method : A New, for Measuring the Electron Density in the Solar Corona (K. E. Machin and F. G. Smith), 599
Radio Spectrum (Galactic) : Observation of a Line in the—Radiation from Galactic Hydrogen at 1,420 Mc./sec. (H. I. Ewen and Prof. E. M. Purcell), 356; (Dr. J. L. Pawsey), 358; The Interstellar Hydrogen Line at 1,420 Mc./sec., and an Estimate of Galactic Rotation (C. A. Muller and Prof. J. H. Oort), 357
Radio Stars : An Accurate Determination of the Positions of Four (F. G. Smith), 555
  An Attempt to Measure the Annual Parallax or Proper Motion of Four (F. G. Smith), 962
  A Search for Long-Period Variations in the Intensity of (M. Ryle and B. Elsmore), 555
Radio Waves : A New Measurement of the Velocity of (Comdr. Carl I. Aslakson), 505
Radio Waves (Very-High-Frequency) : Propagation of (E. Heaton Jones), 870
Radio-Astronomy at Manchester, 17
Radioactive Assay : Preparation of Uniform Solid Samples for (Dr. M. L. Wright), 289
Radioactive Chromium Phosphate : Effect of Antihistamine on the Reticulo-endothelial System—Investigation of Reticulo-endothelial Function with the aid of (Dr. Elemér R. Gabrieli), 467
Radioactive Hydrogen : Estimation of, as Tritiobutane in the Geiger Counter (Dr. R. F. Glascock), 121
Radioactive Isotopes : Errors in Determination of Specific Activity and Turnover Rates of (Prof. A. H. Ennor and H. Rosenberg), 199
Radioactive Phosphorus : A Particulate Impurity found in Solutions of (Dr. J. E. Hotchin), 200
Radioactive Silver : Radiochemical Determination of Chromium, Vanadium and Molybdenum by means of (Dr. J. Govaerts and Carlos Barcia-Goyanes), 198
Radioactivity of Potassium-40 : Calibration of Geiger–Müller Liquid Counters by the (Dr. T. A. Chalmers), 870
Radiocarbon : Simple Equipment to Estimate (O. Feldstein and Dr. E. Broda), 599
Radiocarbon Datability of Peat Marl, Caliche and Archaeological Materials (H. H. Bartlett), 725
Radiochemical Determination of Chromium, Vanadium and Molybdenum by means of Radioactive Silver (Dr. J. Govaerts and Carlos Barcia-Goyanes), 198
Radiochemical Techniques in Analysis (Physical Methods Group of the Society of Public Analysts and other Analytical Chemists Discussion on), 153
Radiocrystallographic Study and Molecular Weight of Actinomycin from Streptomyces S-67 (H. Sarlet, J. Toussaint and H. Brasseur), 469
Radiography : Nuclear Reaction (Mats Hillert), 39
Radiotherapy and Cancer, 101
Radiotherapy of Oral Cancer : Researches on the (Constance A. P. Wood and J. W. Boag), 101
Radium E : Existence and Nature of the 'Positive Particles' near a Source of (Dr. F. C. Champion and A. A. Ahmed), 780
Rainfall Region (Low) : Birds of a, *review* by Dr. A. J. Marshall, 441
Raman and Infra-Red Spectra of Germanium Tetrafluoride (A. D. Caunt, L. N. Short and Dr. L. A. Woodward), 557
Ramsay Memorial Fellowships for Chemical Research, 983
Rat : Effects of a Protein-free Diet on the Alkaline and Acid Phosphatase Activity of the Liver of the (J. O. Ely and M. H. Ross), 323
  Handbook of Psychological Research on the (Norman L. Munn), *review* by Alec Rodger, 134
  Histochemical Evidence of the Presence of Acid-Phosphatase-Positive and -Negative Cell Islets in the Adrenal Medulla of the (Dr. O. Eränkö), 250
Rat Diaphragm (Isolated) : Response of the, to Repeated Stimulation (Prof. J. L. D'Silva and Davidson Nicol), 1125
Rat Liver Deoxypentosenucleoprotein : Composition of Histone prepared from (Robert Brunish, DeLores Fairley and Prof. J. Murray Luck), 82
Rats (Adrenalectomized) : Effect of Ascorbic Acid on Skin Permeability in (Bengt H. Persson), 119
Rats (Adult) : Relation between Polyploidy and the Amounts of Deoxynucleic Acid per Nucleus in the Liver and Kidney of (Marion F. Harrison), 248
Rats (Male and Female) : Effect of a Single Injection of Carbon Tetrachloride upon the Activity of the Pseudo-cholinesterase in the Liver and Serum of (Lucy M. Brown and Marion F. Harrison), 83
Raw Materials (Colonial) : The Processing of (Charlotte Leubuscher), 1105
Reaction between Glucose and the Terminal Amino Group of Lysine (R. S. Hannan and C. H. Lea), 744
Reaction of Metmyoglobin with Hydrogen Peroxide (Dr. P. George and D. H. Irvine), 164
Reactions (Organic) : Dangers Attendant on the Use of N-Halogenimides in (Prof. R. H. Martin), 32
  A Name Index of (Prof. T. S. Wheeler and J. E. Gowan), 63
Reactions of N-Halogenamides : Induction Periods in (Prof. P. Goldfinger, P. A. Gosselain and Prof. R. H. Martin), 30
Reactions of Mixtures of Trifluoroacetic Anhydride and Oxy-Acids : Properties of (Dr. E. J. Bourne, Dr. J. E. B. Randles, Dr. J. C. Tatlow and Dr. J. M. Tedder), 942
Reactivity of Free Radicals (Faraday Society General Discussion on), 63
Receptor-destroying Enzyme : Protection by, against Infection with a Neurotropic Variant of Influenza Virus (H. J. P. Cairns), 335
Recombination Values in the Sixth Chromosome of the House Mouse : A Pronounced Sex Difference in (S. A. Mallyon), 118
Reduction of Ferrous Oxide (O. H. Gellner and Dr. F. D. Richardson), 23
Redwood Lecture of the Institute of Petroleum (Prof. F. H. Garner), 724
Reflexion Factor : Spectral, of the Cat's Tapetum (R. Gunter, H. G. W. Harding and Dr. W. S. Stiles), 293
Refractometer : A Highly Sensitive Phase-Contrast, for Liquids and Gases (Erik Ingelstam), 960
Refrigeration : Eighth International Congress of (Dr. G. G. Haselden), 806
Regeneration of the Corneal Epithelium of Rabbits : Electric Shock and the (Margarete Holzbauer and Prof. R. Rigler), 919
'Regular Solution' : The Term (Prof. Joel H. Hildebrand), 868
Reichstein's Compound *D* : Cortical Hormones from *allo*Steroids—Synthesis of Cortisone from (Dr. G. Rosenkranz, Dr. Carl Djerassi, R. Yashin and J. Pataki), 28
Reith Lectures of the B.B.C., 1950 (Prof. J. Z. Young), *review* by Prof. S. Zuckerman, 1095
Relativitätstheorie : Weltsystem, Weltäther und die (Prof. Dr. Karl Jellinek), *review* by Prof. H. T. H. Piaggio, 353
Relativity (Kinematic) : Gravitation in (Prof. A. G. Walker), 961
Relativity for Experimental Physicists, *review* by Prof. H. T. H. Piaggio, 353
Relativity Theory : The Clock Paradox in (Dr. Herbert E. Ives), 246
Relaxation : Active, of Unstriated Muscle produced by Adrenaline (Sunita Inderjit Singh and Prof. Inderjit Singh), 829
Relaxation Methods : Summer School on (Imperial College of Science and Technology), 236
Religion : Science and, 235
  Science and, *review* by the Very Rev. W. R. Matthews, 968
Repetitive Trains of Auditory 'Click' Stimuli : Tone Sensation produced by (W. T. Catton), 882
Representation : The Clear, of Very Small Masses (N. W. Pirie), 1008
Reproductive Organs of Near-Term and New-Born Seals (Prof. E. C. Amoroso, Dr. R. J. Harrison, Dr. L. Harrison Matthews and Dr. I. W. Rowlands), 771

Requirements : Specific, for the Action of Deoxyribonuclease (Dr. Christoph Tamm and Prof. Erwin Chargaff), 916
Research : Agricultural, in the Groundnut Scheme, 1947–51 (Dr. A. H. Bunting), 804
  Cancer, in Great Britain, 417
  Forest, in Sweden, 777
  Industrial, in East Africa, 319
  Industrial, in Switzerland (Prof. Ronald S. Edwards and Charles La Roche), *review* by R. Brightman, 398
  Instructional Film, in Pennsylvania (C. Denis Pegge), 775
  Medical, in East Africa, 898
  Scientific, in Industry in Belgium, 420
  Technological, in Switzerland, *review* by R. Brightman, 398
  Voluntary Bodies and the Support of, 349
Research 1950–51 : Colonial (Colonial Office), 815
Research (Biological) : Some Aspects of, in the Soviet Union (Science Section of the Society for Cultural Relations between the Peoples of the British Commonwealth and the U.S.S.R. Meeting on), 814
Research (Chemical) : Ramsay Memorial Fellowships for, 983
Research (Civilian Scientific) · Government Responsibility in, 481
Research (Defence) : Scientific Workers and, in the United States, 857
Research (Industrial and Scientific) : International Symposium on the Organization of (Department of Scientific and Industrial Research), 814
Research (Psychological) : Handbook of, on the Rat (Norman L. Munn), *review* by Alec Rodger, 134
Research in the University of Birmingham, 62
Research on Brick-Making, 331
Research in Oceanography (L. H. N. Cooper), 184
Research and Additions to the British Flora : Recent (J. E. Lousley), 934
Research Activities of the D.S.I.R. and the Research Associations : Brief Guide to the (Department of Scientific and Industrial Research), 455
Research Discussions on Engineering Technology (Departments of Civil and Mechanical Engineering of the University of Nottingham), 455
Research Fellowship : Knoop, in Economics at the University of Sheffield awarded to D. C. Corner, 726
  John Stokes, of the University of Sheffield awarded to N L. Kornberg, 726
Research Fellowships (National Institute of Sciences of India), 498
Research Fellowships 1951 : Leverhulme, 19
Research Scholarships (Royal Society), 144
Research Studentships for postgraduate training in ecology (Nature Conservancy), 984
Research and Development (Scientific) : The Balance of, 615
Research and Development in British Colonial Territories, 691
Research and Development in British Colonies 1950–51, 815
Research and Development in the Simon Engineering Group (Dr. W. Rheinallt Thomas), 284
Researches : Fisheries, in Singapore Straits, 640
Researches in Physics : Recent, *review* by S. Weintroub, 484
Reservoirs (British) : Silting in (R. M. Prothero), 27
Resin Adhesives (Synthetic) : Technology of (Aero Research, Ltd., Summer School on), 236
Resins (Phenolic) : Chemistry of, *review* by N. J. L. Megson, 215
Resistance of Bacterial Cells : Variation with Age in the (Dr. Helen R. White), 828
Resistance to Insecticide in Houseflies : Mechanism of (Dr. J. R. Busvine), 193
Resistant Membrane in Wool (Dr. P. Alexander), 1081
Resistant Peripheral Membranes of the Keratin Fibres (Dr. E. H. Mercer), 824 ; (Dr. C. H. Bamford, Dr. A. Elliott and W. E. Hanby), 824
Resistivity of Gold Change of, by Cold-working at Liquid-Air Temperature and its Recovery by Temporary Heating (Prof. M. J. Druyvesteyn and J. A. Manintveld), 868
Resolution of the Specific Granules of the Islets of Langerhans : Fluorochromy as an Aid in the (Dr. W. Stanley Hartroft), 1000
Respiratory Blood Pigments in *Serpula* : Oxygen Affinities of (Prof. H. Munro Fox), 112
Reticulo-endothelial System : Effect of Antihistamine on the—Investigation of Reticulo-endothelial Function with the aid of Radioactive Chromium Phosphate (Dr. Elemér R. Gabrieli), 467
Reversion-rate of a Serineless *Escherichia coli* Mutant : Enhancement of the Normal, by certain Organic Acids (Dr. Barbara E. Wright), 1087
Reviews of Pure and Applied Chemistry (Royal Australian Chemical Institute), First Issue, 188
Rf Values of the Amino-acids during Paper Chromatography with Solvents completely Miscible with Water : Effect of Temperature on the (D. P. Burma), 565
Rh Chromosome CwdE (*Ryw*) occurring in Three Generations (L. Dunsford and P. Aspinall), 954
Rheology of Films and Surfaces (British Society of Rheology and the Local Section of the Chemical Society Conference on, at University College, Exeter), 369, 945
Rheumatoid Connective Tissue : Biophysical Studies of (Dr. J. H. Kellgren and Dr. J. Ball, and Prof. W. T. Astbury, Dr R. Reed and E. Beighton), 493
Rhodanine Derivatives : Mildew-preventing Activity of (Frances C. Brown and Dr. Charles K. Bradsher), 171
Rhodnius : Source of Moulting Hormone in (Dr. V. B. Wigglesworth), 558
Rhododendron Leaf : The (Dr. John Macqueen Cowan), *review* by Prof. J. McLean Thompson, 5
Ribonucleic Acid : Structure of (Dr. Roy Markham and Dr. J. D. Smith), 406
Ribosidation of 4-Amino-imidazole-5-carboxamide by *Escherichia coli* (R. Ben-Ishai, Dr. Ernst D. Bergmann and B. E. Volcani), 1124
Rice Grains : Growth Hormones of, Germinated at Different Temperatures (Prof. S. M. Sircar and T. M. Das), 382
Rice Plants : Effect of Nitrogen-fixing Blue-Green Algae on the Growth of (Dr. A. Watanabe, S. Nishigaki and C. Konishi), 748
Richtmyer Memorial Lecture of the American Association of Physics Teachers (Prof. J. C. Slater), 156
Rock : Artificial, for Display Purposes (W. T. Stirling), 455
Rockefeller Travelling Fellowships in Medicine (Medical Research Council Awards), 189
Rocks : Remanent Magnetism of, and the History of the Geomagnetic Field (J. Hospers), 1111
Rocks (Carbonate) : Relative Abundances of Oxygen and Carbon Isotopes in (Dr. P. Baertschi), 288
Rodiyas : Cultural Anthropology of the (M. D. Raghavan), 813
Romanes Lecture (Lord Hankey), 571
Root of It All : At the (W. E. Dick), 899
Root Cuttings : Vegetative Propagation by (António Correa de S. Castelo Branco), 125
Root System of the Oil Palm of West Africa : Unusual Features of the (J. O. Wright), 748
Ross and Cromarty: Nature Reserve in, 938
Rotatory Dispersion Measurements with a Unicam Spectrophotometer (Dr. Stotherd Mitchell and James Veitch), 662
Royal Head from Ancient Egypt (Dr. George Steindorff), 499
Royal Medals for 1951 of the Royal Society awarded to Sir Howard Florey and Sir Ian Heilbron, 897, 1017
Rubidium-86 · Nuclear Spin of (E. H. Bellamy), 556
Rubidium Iodide on a Barium Stearate Substrate deposited on Mica : Epitaxis of (A. A. Fuller), 471, 899
Runs in a Sequence of Observations (Prof. P. V. Krishna Iyer and A. S. Prakash Rao), 557 ; *erratum*, 770
Rural Life at Home and Overseas (Institute of Rural Life at Home and Overseas Conference on), 940
Rutherford Memorial Appeal in New Zealand, 1066

SACCHARUM : Chromosome Elimination in (Dr. N. Parthasarathy), 383
Sacral Ribs of Lacertilia (Dr. Abdel Halim Kamel), 660
Safety in the Laboratory (Dunlop Rubber Co., Ltd., Manual on), 188
Safety Problems of Nuclear Technology . Industrial and (edited by Prof. Morris H. Shamos and Prof. Sidney G. Roth), *review* by Sir John Cockcroft, 263
Safety and Hygiene in Chemical Industry from the Point of View of the Manager, Technician and Operative (Sindicato Vertical de Industrias Quimicas Conference on), 641
Salt : Influence of, on the Size and Shape of a Protein–Detergent Complex (J. A. Friend, B. S. Harrap and Dr. J. H. Schulman), 910
Salters' Fellowships for 1951–52 awarded to Dr. A. P. C. Cumming and Raymond Grafton, 641
Salters' Scholarship for 1951–52 awarded to Malcolm McLeman, 641
Salts (Inorganic) : Modification of Crystal Habit of, with Dyes (Dr. J. Whetstone), 663
Samoa : Mygalomorph Spider in (Prof. B. J. Marples), 300
Samples (Uniform Solid) : Preparation of, for Radioactive Assay (Dr. M. L. Wright), 289
Sampling Method : Improved, for Demonstration of Local Antibodies in the Vagina (Dr. L. Szabó), 171
Sannhemp (*Crotalaria juncea* Linn.) Mosaic Virus : Structure of, with the Electron Microscope (Dr. N. N. Das Gupta, M. L. De and S. P. Raychaudhuri), 114
Saturation (Base) : Relationship between, and Crop Response to Phosphate in Acid Soils (Dr. H. F. Birch), 388
Scattering of Cold Neutrons Inelastic (P. A. Egelstaff), 290
Scattering of 146-MeV. Protons by Deuterons (J. M. Cassels, G. H. Stafford and Dr. T. G. Pickavance), 556
Schirmung in der Fern- und Hochfrequenztechnik : Die elektromagnetische (Dr. Heinrich Kaden), *review* by R. E. Burgess, 717
Scholarship : Salters', for 1951–52, 641
Scholarship Awards : Postgraduate Agricultural (Ministry of Agriculture and Fisheries), 683
Scholarships : Inter-Commonwealth Postgraduate, in Science, 938
  Postgraduate Agricultural (Department of Agriculture for Scotland Awards), 589
  Research (Royal Society), 144
  Travelling, in Medical Science (Medical Research Council Awards), 189
School : Children Out of (Joy C. Ward), 649
'Scicong' Memoranda for Unesco (Indian Science Congress Association), 589
Science · Inter-Commonwealth Postgraduate Scholarships in, 938
  Doubt and Certainty in (Prof. J. Z. Young), *review* by Prof. S. Zuckerman, 1095
  Fifty Years of Progress in, *review* by W. L. Sumner, 214
  The 1951 Exhibition of (G. R. Noakes), 69
  Inventories of Apparatus and Materials for Teaching, Vol. 2, Universities (Unesco), 102
  Louis Pasteur, Free Lance of (René J. Dubos), *review*, 50
  Security, Loyalty and (Prof. Walter Gellhorn), 305
  Spotlight on (Dr. J. Gordon Cook), 17
  The World of (Dr. F. Sherwood Taylor), second edition, *review* by Dr. H. R. Lang, 532
Science in American Education : Importance of (Ernst A. Hauser), 866
Science in Berlin (Dr. F. P. Bowden), 237
Science on Farming : Impact of, *review*, 670
Science and the Glasshouse (William J. C. Lawrence), second edition, *review* by Wilfred Corbett, 397
Science and Art of Government (Lord Hankey), 571
Science and Industry : Quakers in (Dr. Arthur Raistrick), *review* by V. A. Eyles, 94
Science and the Layman, 213
Science and Religion, 235
Science and Religion, *review* by the Very Rev. Dr. W. R. Matthews, 968
Science and Technology in the Past Hundred Years : The British Contribution to (H.R.H. the Duke of Edinburgh), 219
Science and Technology in India and Southeast Asia : History of (Dr. Joseph Needham), 64, 1048 ; (Dr. S. L. Hora), 1047
Science and Tribal Art (William Fagg), 1099
Science Abstracting, International Conference on : Final Report, 1105
Science Teaching : Aids to, 102
Scientific Advisers for Civil Defence, 984
Scientific Management (T. H. Hawkins), 506
Scientific Organization : Government, in the Civilian Field, 482
Scientific Outlook in 1851 and in 1951 (Prof. H. Dingle), 725
Scientific Photography, *review* by L. V. Chilton, 485

Scientific Popularization : Kalinga Prize for (established by M. B. Patnaik), 19
Scientific Research (Civilian) : Government Responsibility in, 481
Scientific Research in Industry in Belgium, 420
Scientific Research and Development : The Balance of, 615
Scientific Shrines : British (Eng.-Capt. Edgar C. Smith), (5), 180 ; (6), 443; *erratum*, 589 ; (7), 578
Scientific Survey of South-Eastern Scotland, *review*, 972
Scientific Thought in the Twentieth Century (edited by Prof. A. E. Heath), *review* by W. L. Sumner, 214
Scientific Translations : Commonwealth Index of, 235
Scientific Worker : Ethical Problems of the (Cambridge Branch of the Association of Scientific Workers Conference on), 1112
Scientific Workers and Defence Research in the United States, 857
Scientific and Industrial Research : International Symposium on the Organization of (Department of Scientific and Industrial Research), 814
Scientific and Learned Societies of Great Britain, 57th edition, *review*, 218
Scotland : Animals of (Glasgow Art Gallery and Museum Booklet on), 413
Scotland (South-Eastern) : Scientific Survey of, *review*, 972
Scots Pine in Great Britain : General Volume Tables for (F. C. Hummel, T. W. Irvine and J. Jeffers), 111
Scottish Highlands : Human Problems of the, 191
Scottish Scene : The (Dr. Douglas A. Allan), 233
Screw Dislocation : Polymorphism arising from (Dr. V. Vand), 783
Sea : Sonic Layers in the (B. B. Parrish and R. E. Craig), 472
Sea (Shallow) : Life of the Shore and (Dr. Douglas P. Wilson), second edition, *review* by Dr. N. B. Eales, 1014
Sea as exemplified by the English Channel : Influences of Tidal Streams on Oceanographic and Climatic Conditions in the (Dr. G. Dietrich), 8
Sea Water : Sulphur from (Prof. Hugh Nicol), 894
Seals (Near-Term and New-Born) : Reproductive Organs of (Prof. E. C. Amoroso, Dr. R. J. Harrison, Dr. L. Harrison Matthews and Dr. I. W. Rowlands), 771
Secretions of the Pancreas of the Dog and Parotid of the Pig : Cholinesterase Activity in the (Prof. R. A. McCance, L. M. Brown, Dr. R. S. Comline and D. A. Titchen), 788
Security, Loyalty and Science (Prof. Walter Gellhorn), 305
Sedimentation in the Tropical Indian Ocean (W. R. Riedel), 737
Seed Pathology (Dr. Mary Noble), 534
Seed Plants : Embryonic Development in the, *review* by Prof. R. C. McLean, 619
Seeds (Watercress) : Effect of Light on the Germination of (H. W. Howard and A. G. Lyon), 253
Seismology : Bibliography of, 1106
Selenium Toxicity associated with an Irish Soil Series (T. Walsh, G. A. Fleming, R. O'Connor and A. Sweeney), 881
Semen (Rabbit) : The Gelatinous Mass in (Dr. D. P. Mukherjee, M. P. Johari and P. Bhattacharya), 422
Seminal Vesicle Secretion : Ergothioneine in the (Dr. E. Leone and Dr. T. Mann), 205
Seminal Vesicle Secretion of the Boar : Inositol, a Major Constituent of the (Dr. T. Mann), 1043
Senses and Behaviour of Animals (British Association, Sections D (Zoology) and J (Psychology), Discussion on), 643
Sensitivity to Tuberculin (Dr. C. N. D. Cruickshank), 206
Sensory Organs in *Xenopus laevis* Daudin : New Lateral Line (E. Elkan and R. W. Murray), 477
Sequence of Observations : Runs in a (Prof. P. V. Krishna Iyer and A. S. Prakash Rao), 557 ; *erratum*, 770
Sera : An Electrophoresis Apparatus for Analysing several, Simultaneously (Dr. A. Polson), 996
Sericin (Silk) : Amino-acids of (J. T. B. Shaw and Dr. S. G. Smith), 745
Serineless *Escherichia coli* Mutant : Enhancement of the Normal Reversion-rate of a, by certain Organic Acids (Dr. Barbara E. Wright), 1087
Serological Studies : Preparation of the Specific Purified Antigen of Canine Hepatitis Virus and Antiserum for (Dr. N. M. Larin), 745
'Serotonin' in Serum : Source of (M. Rand and Dr. G. Reid), 385
Serpula : Oxygen Affinities of Respiratory Blood Pigments in (Prof. H. Munro Fox), 112
Serum : Source of 'Serotonin' in (M. Rand and Dr. G. Reid), 385
Serum (Antilymphocytic) : Effect of, on Suspensions of Lymphocytes *in vitro* (Dr. Michael Woodruff and Bruce Forman), 35
Serum of Male and Female Rats : Effect of a Single Injection of Carbon Tetrachloride upon the Activity of the Pseudo-cholinesterase in the Liver and (Lucy M. Brown and Marion F. Harrison), 83
Serum Albumin of Animals : Effect of Diseases on the (A. Polson), 421
Sex Difference : A Pronounced, in Recombination Values in the Sixth Chromosome of the House Mouse (S. A. Mallyon), 118
Sex-Ratio at Birth in Man : ABO Blood Groups and (Dr. L. D. Sanghvi), 1077
Sexual Season of the Ewe : Inhibitory Action of Artificial Light on the (Dr. E. S. E. Hafez), 336
Sexual Season in Ewe Lambs (Dr. E. S. E. Hafez), 1046
Shadowgraphs of Oat Seedlings : A Technique for taking Successive (Dr. O. V. S. Heath), 950
Shape of a Protein–Detergent Complex : Influence of Salt on the Size and (J. A. Friend, B. S. Harrap and Dr. J. H. Schulman), 910
Shear's Polysaccharide : Effect of, on Plasma Clotting (Sylvia Most), 342
Sheep : A New Species of *Nematodirus* in (Dr. H. D. Crofton and R. J. Thomas), 559
  Is Age of Parents Important in (R. A. Barton), 37
  A New Biological Method for Evaluating the Efficiency of Insecticides for the Protection of, against Blowfly Strike (O. G. H. Fiedler and R. du Toit), 608
Sheep Abortion Virus : Use of a, as a Test Virus for Chemotherapy Work (Dr. Lois Dickinson and G. W. Inkley), 37
Shipbuilding (International Conference of Naval Architects and Marine Engineers on), 415
Shore and Shallow Sea : Life of the (Dr. Douglas P. Wilson), second edition, *review* by Dr. N. B. Eales, 1014
Shrike : Isabelline, on the Isle of May, 939
Shrimps' : 'Opossum, *review* by Dr. W. T. Calman, 924
Shrubs : Pests of Flowers and (G. Fox Wilson), second edition, 321
Sidey Medal and Prize for 1951 of the Royal Society of New Zealand awarded to Prof. V. A. Bailey, 726
Sigma Phase : The Xi-Phase and a New (D. Summers-Smith), 786
Silage (Dr. Stephen J. Watson and Dr. A. M. Smith), *review* by Prof. H. G. Sanders, 620
  Chemistry and Bacteriology of-(Society for Applied Bacteriology Symposium on), 730
  Estimation of Volatile Fatty Acids and Ammonia in, by means of Paper Chromatography (Prof. Artturi I. Virtanen and Jorma K. Miettinen), 294
Silicate Minerals : The Colloid Chemistry of the (Prof. C. Edmund Marshall), *review*, 577
Silk Fibre : Formation of, by the Silkworm (Dr. E. H. Mercer), 792
Silk Sericin : Amino-acids of (J. T. B. Shaw and Dr. S. G. Smith), 745
Silkworm : Formation of Silk Fibre by the (Dr. E. H. Mercer), 792
Silting in British Reservoirs (R. M. Prothero), 27
Silver (Radioactive) : Radiochemical Determination of Chromium, Vanadium and Molybdenum by means of (Dr. J. Goverts and Carlos Barcia-Goyanes), 198
Silver and Bronze : Tarnish and Corrosion of, 639
Simms Gold Medal of the Royal Aeronautical Society awarded to Dr. G. S. Hislop, 498
Simon Engineering Group : Research and Development in the (Dr. W. Rheinallt Thomas), 284
Singapore Straits : The Food and Feeding Relationships of the Fishes of (Tham Ah Kow), 640
Size and Shape of a Protein–Detergent Complex : Influence of Salt on the (J. A. Friend, B. S. Harrap and Dr. J. H. Schulman), 910
Skeletal Structures : Differentiation of, from Mouse Embryo Mince in the Peritoneum of Adult Mice (Theodore S. Hauschka), 1130
Skin (Human) : Occurrence of Thin Membranes in the Surface Layers of, and in Finger Nails (Gosta Lagermalm, Bo Philip and Joel Lindberg), 1080
Skin (Mammalian) : Extraction of Chloride from (Dr. M. Grace Eggleton), 660
Skin Permeability in Adrenalectomized Rats : Effect of Ascorbic Acid on (Bengt H. Persson), 119
Sky : The Night, in August, 147 ; in September, 369 ; in October, 545 ; in November, 726 ; in December, 940
Sky (Night): Atmospheric Oxygen Bands in Emission from Neon–Oxygen Mixtures, and in, and Auroral Luminescences (G. Kvifte), 741
Slow-Neutron Ternary Fission of Uranium-235 (Prof. E. W. Titterton), 590
Smell : Localization of Gustatory and Olfactory Enzymes in the Rabbit, and the Problems of Taste and (A. F. Baradi and Dr. G. H. Bourne), 977
Smithsonian : The, America's Treasure House (Webster Prentiss True), *review* by Dr. F. S. Wallis, 888
Snow in Museum Displays : Representation of (W. T. Stirling), 145
Soaps : Methods for the Analysis of (British Standard 1715 : 1951), 683
Social Action: Social Surveys and (Mark Abrams), *review* by Prof. T. H. Marshall, 847
Social Consequences of Pneumoconiosis among Coalminers in South Wales (Dr. P. Hugh-Jones and Dr. C. M. Fletcher), 1106
Social Equilibrium : Physics of (Prof. T. S. Simey), 546, 1049 ; (Dr. R. Fürth), 1048
Social Structure : Fear and (Dr. Grantly Dick Read), 413
Social Studies : Anthropology and, *review* by Mrs. Mary Douglas, 799
Social Surveys and Social Action (Mark Abrams), *review* by Prof. T. H. Marshall, 847
Social Work : International Survey of Training for (United Nations Department of Social Affairs), 544
Society, an Introductory Analysis (Prof. R. M. MacIver and Prof. Charles H. Page), *review* by Mrs. Mary Douglas, 799
  The Human Use of Human Beings—Cybernetics and (Prof Norbert Wiener), *review* by F. I. G. Rawlins, 442
Society under the Microscope, *review* by Prof. T. H. Marshall, 847
Sodium Acetylide in Liquid Ammonia: Tetrabromothiophene from 2-Bromothiophene by means of (A. Vaitiekunas and Prof. F. F. Nord), 875
Sodium Gentisate : Determination of, by Chromatography and Fluorescence (Dr. L. Nanninga and B. Bink), 389
Sodium Thymonucleate : Viscosity of (Dr. Sadhan Basu), 341
Soil : 'Double-Action' of Trichothecin and its Production in (D. G. Hessayon), 998
  Microbiological Oxidation of Ammonium and Thiocyanate Ions in (Dr. H. Gleen), 117
Soil Science : M. Theodore Kearney Foundation of, endowed in the College of Agriculture of the University of California, 938
Soil Series (Irish) : Selenium Toxicity associated with an (T. Walsh, G. A. Fleming, R. O'Connor and A. Sweeney), 881
Soil Survey of Great Britain, 1105
Soil and Climatic Factors : Plant and Animal Nutrition in relation to (British Commonwealth Scientific Official Conference Specialist Conference in Agriculture, Australia 1949, Proceedings), 499
Soil and Freshwater Nematodes (Dr. T. Goodey), *review* by Prof. C. H. O'Donoghue, 801
Soil-extract Responsible for Bacterial Growth-stimulation : Nature of the Factor in (Dr. C. B. Taylor), 115
Soils (Acid) : Relationship between Base Saturation and Crop Response to Phosphate in (Dr. H. F. Birch), 388
Sol-type and Gel-type Gelatine Films : Mechanical Properties and Structure of (E. Bradbury and C. Martin), 837
Solar Corona : A New Radio Method for Measuring the Electron Density in the (K. E. Machin and F. G. Smith), 599
Solid Phase Determinations in the System Aluminium Sulphate/Sulphuric Acid/Water using Tracer Technique (Duncan Taylor and Richard Scott), 520
α-Solid Solutions of Copper : Mechanical Properties of, with Zinc, Gallium, Germanium and Arsenic (Dr N. P. Allen, T. H. Schofield and A. E. L. Tate), 378
Solidification Curves and Crystal Spacings of Binary Fatty-acid Mixtures (M. Fieldes and L. Hartman), 74
Solidifications of Castings (R. W. Ruddle), *review* by Prof. F. C. Thompson, 218
Solubility of Ethylenediamine D-Tartrate in Water (L. A. Dauncey and J. E. Still), 34
Solutions : Statistical Theory of (Dr. A. B. D. Cassie), 382
Solutions of Polyisobutylene : Measurements of the Normal Stress Effect in (H. W. Greensmith and R. S. Rivlin), 664
Solvent : Urea as a (Dr. Robert E. D. Clark), 876

Solvent Systems (Buffered) : Application of, to the Detection of Aromatic Acids by Paper Partition Chromatography (Mona E. Fewster and Dr. David A. Hall), 78
Solvents (Dr. Thos. H. Durrans), sixth edition, *review* by E. H. Nurse, 7
  Industrial (Ibert Mellan), second edition, *review* by Prof. H. E. Watson, 311
Solvents (Non-Aqueous) : Dissociation of Complex Ions in (Dr. F. P. Dwyer and N. A. Gibson), 787
Solvents completely Miscible with Water : Effect of Temperature on the R_F Values of the Amino-acids during Paper Chromatography with (D. P. Burma), 565
Sonic Layers in the Sea (B. B. Parrish and R. E. Craig), 472
Sound : Light and (M. Nelkon), *review*, 7
Sound in Aqueous Solutions of Electrolytes : Absorption of (K. Tamm and G. Kurtze), 346
Sound Waves in a Ferromagnetic Material : Effect of a Magnetic Field on the Propagation of (J. de Klerk), 963
South American Indians : Handbook of (edited by Julian H. Steward), Vol. 6, *review* by Dr. G. H. S. Bushnell, 575
Soviet Union : Some Aspects of Biological Research in the (Science Section of the Society for Cultural Relations between the Peoples of the British Commonwealth and the U.S.S.R. Meeting on), 814
Spanish Broom : Isolation of Octadecan-1 : 18-diol from (Dr. O. C. Musgrave, James Stark and Prof. F. S. Spring), 298
Spark Gaps : Cold Emission of Electrons in (Prof. F. Llewellyn Jones and Dr. E. T. de la Perrelle), 160
Spartina townsendii (Groves) : New Forms of (E. H. Chater and H. Jones), 126
Specific Activity and Turnover Rates of Radioactive Isotopes : Errors in Determination of (Prof. A. H. Ennor and H. Rosenberg), 199
Spectra of Flames burning with Oxides of Nitrogen (B. B. Fogarty and H. G. Wolfhard), 1122
Spectrochemical Analysis, *review* by Dr. A. G. Gaydon, 5
Spectrometer : An Interference, for the Infra-Red (J. H. Jaffe), 381
Spectrometer (Littrow-type Infra-Red) · Improving the Performance of a (J. C. O. Rochester and Dr. A. E. Martin), 785
Spectrophotometer (Unicam) : Rotatory Dispersion Measurements with a (Dr. Stotherd Mitchell and James Veitch), 661
Spectrophotometric Determination of Hæmoglobin in Blood (A. A. Khalifa and Prof. M. K. Salah), 915
Spectrophotometry . Pure *All-trans* Vitamin A Acetate and the Assessment of Vitamin A Potency by (J. Boldingh ; H. R. Cama, Dr. F. D. Collins and Prof. R. A. Morton ; N. T. Gridgeman ; O. Isler and M. Kofler ; R. J. Taylor ; A. S. Welland and T. Bradbury), 598
Spectroscopy, British Bulletin of, 982
Spectroscopy · Metal (F. Twyman), *review* by Dr. A. G. Gaydon, 5
Speech and Thought : Freedom of, 305
Speed : World Communications—The Impact of (British Association (Division for Social and International Relations of Science), Discussion on), 446
Spermatheca in Sucking Louse (D. Mukerji and P. Sen Sarma), 612
Spermatozoa deposited into the Fallopian Tubes : Fertilizing Capacity of (Dr. M. C. Chang), 697
Spherical Aberrations are Known · A Formula for determining the Wave-Surface if the (Dr. F. I. Havlicek), 743
Spider in Samoa : Mygalomorph (Prof. B. J. Marples), 300
Spiders : British (G. H. Locket and Dr. A. F. Millidge), Vol. I, *review* by T. H. Savory, 714
Spiders of Britain, *review* by T. H. Savory, 714
Spiral Patterns . Growth, on Carborundum Crystals (Ajit Ram Verma), 783
Spiritual Life : Natural Science and the (Rev. John Baillie), *review* by the Very Rev. Dr. W. R. Matthews, 968
Splenogenic Anæmia in the Rabbit : Surgically induced (Kurt I. Altman, Robert N. Watman and Kurt Salomon), 827
Spore-formation in Yeast : The Cement Block, an Improved Block for (V. Hartelius and E. Ditlevsen), 385
  An Improved Block for (Dr. E. Elion), 1130
Sporogonic Development of *Plasmodium berghei* in Experimentally Infected *Anopheles* spp. : Complete (Dr. M. Yoeli and Miss W. J. Wall), 1078
Spotlight on Science (Dr. J. Gordon Cook), 17
Standards : Recent Developments and Techniques in the Maintenance of (National Physical Laboratory Symposium on), 594
Standing-Waves in Low-Energy Electron Beams (Dr. W. W. H. Clarke and Dr. L. Jacob), 1120
Star-producing Radiation : Transition Effect of the (L. Tomášková), 1005
Starch : Chemistry and Industry of (edited by Dr. Ralph W. Kerr), second edition, *review* by Prof. R. H. Hopkins, 179
  Pure and Applied Chemistry of, *review* by Prof. R. H. Hopkins, 179
Stars : Hydrogen Exhaustion and Explosions of (Dr. G. Gamow), 72
Stars (Radio) An Accurate Determination of the Positions of (F. G. Smith), 555
  An Attempt to Measure the Annual Parallax or Proper Motion of Four (F. G. Smith), 962
  A Search for Long-Period Variations in the Intensity of (M. Ryle and B. Elsmore), 555
State (Modern) : Leadership in the, 571
State (Welfare) : Leadership in the, 1093
Static Electrification : Reduction of, by means of Inhibiting Compounds (G. W. Graham), 871
Statistical Inference in Dynamic Economic Models (edited by Tjalling C. Koopmans), *review*, 620
Statistical Methods . The Application of, to Chemistry (London and South Eastern Counties Section of the Royal Institute of Chemistry Discussion on), 1072
Statistical Methods in Anthropology (Dr. J. Bronowski and W. M. Long), 794 ; (Dr. F. Yates and M. J. R. Healy), 1116 ; (E. H. Ashton and Prof. S. Zuckerman), 1117
Statistical Theory of Solutions (Dr. A. B. D. Cassie), 382
Statistics (Dr. N. L. Johnson and H. Tetley), Vol. 2, *review*, 486
  Introduction to the Theory of Probability and (Prof. Niels Arley and Prof. K. Rander Buch), *review* by David G. Kendall, 217
Statistics (Mathematical) : Contributions to (Prof. R. A. Fisher), *review* by Dr. F. Yates, 308
Statistics at the Australian National University, 320
Steel Carbide (High-speed) : Metallic Oxides with the Structure of (Nil Karlsson), 558
Stereochemistry of Gold (R. S. Nyholm), 705
Stereoisomers of *iso*Leucine : Enzymatic Conversion of the, to the Corresponding α-Keto-Acids (Dr Alton Meister), 1119
Sterility : Infertility and (American Society for the Study of Sterility prize for an essay on), 858
Sterling (Louis) Premium of the British Institution of Radio Engineers awarded to J. E. B. Jacob, 413
*allo*Steroids · Cortical Hormones from—Synthesis of Cortisone from Reichstein's Compound *D* (Dr. G. Rosenkranz, Dr. Carl Djerassi, R. Yashin and J. Pataki), 28
Sterol : Mould Lipase—Effect of Addition of Vitamins and, to the Cake Medium on the Growth and the Activity of the Lipolytic Mould (Dr. C. V. Ramakrishnan and Prof. B. N. Banerjee), 917
Stimulation (Repeated) · Response of the Isolated Rat Diaphragm to (Prof. J. L. D'Silva and Davidson Nicol), 1125
Stokes (John) Research Fellowship of the University of Sheffield awarded to H. L. Kornberg, 726
Stone-loach : Toxicity of Copper in Solution to the (F. J. Mackereth and W. J. P. Smyly), 1130
Stonehenge : A Rare Alga from (M. A. Pocock), 524
Storage of Farm Products (British Association, Section M (Agriculture), Discussion on), 488
Stratosphere Air : Variation in the Chemical Composition of (Dr. K. F. Chackett, Prof. F. A. Paneth, P. Reasbeck and B. S. Wiborg), 358
Streptococci (Lactic). 'Streptozyme', a Lytic Enzyme from (Dr. A. Hirsch and Dorothy M. Wheater), 607
Streptomyces S-67 : Radiocrystallographic Study and Molecular Weight of Actinomycin from (H. Sarlet, J. Toussaint and H Brasseur), 469
'Streptozyme', a Lytic Enzyme from Lactic Streptococci (Dr. A. Hirsch and Dorothy M. Wheater), 607
Stress Analysis (Stress Analysis Group of the Institute of Physics Conference on), 734
Stress Effect (Normal) : Measurements of the, in Solutions of Polyisobutylene (H. W. Greensmith and R. S. Rivlin), 664
Strukturchemie : Anorganische (Prof. W. Hückel), *review* by Prof. E. G. Cox, 756
Structure of Clathrate Compounds (H. M. Powell), 11
Structure of Dry β-Lactoglobulin Crystals : Crystal Structure of a Low Molecular Weight Protein— (Dr. D. P. Riley), 242
Structure of Sannhemp (*Crotalaria juncea* Linn.) Mosaic Virus with the Electron Microscope (Dr. N. N. Das Gupta, M. L. De and S. P. Raychaudhuri), 114
Structure of Sol-type and Gel-type Gelatine Films : Mechanical Properties and (E. Bradbury and C. Martin), 837
Structure of Synthetic Polypeptides and Proteins (Dr. C. H. Bamford and W. E. Hanby), 340
Structure of Yeast Cell Walls · Composition and (A. L. Houwink, D. R. Kreger and P. A. Roelofsen), 693
Structures of Uranium (Dr. J. Thewlis), 198
Stuart (Herbert Ackroyd) Memorial Prize of the Royal Aeronautical Society awarded to A. V. Cleaver, 498
Student Health (British Association, Section I (Physiology), Symposium on), 503
Student-Health Services, 320
Studentships : Research, for postgraduate training in ecology (Nature Conservancy), 984
Subject Index to Periodicals, 1949 (Library Association), *review*, 486
Submicroscopic Structure of Fibres and their Formation (Dr. Edgar Ribi), 1082
Succinate Oxidation in Brain : Glucose, Glutamate and (Dr. H. Harris, Dr. E. M. Trautner and M. Messer), 914
Sucrose : The Structure and Configuration of (Dr. I. Levi and Prof. C. B. Purves), 103
Sugar Absorption : Effect of Phosphates and the *p*H on (Prof. F. Ponz and J. Larralde), 912
Sugar-cane . Intraseasonal Growth Variation and Cultivation of (Dr. C. V. Krishna Iyengar), 252
Sugars : A Colorimetric Method for the Determination of (M. Dubois, K. Gilles, J. K. Hamilton, P. A. Rebers and Prof. F. Smith), 167
  Detection of, by Paper Chromatography (R. J. Bayly, Dr. E. J. Bourne and Prof. M. Stacey), 510
  The Synthesis and Functions of, in Plant Life (Prof. E. L. Hirst), 61
Sulphate-reducing Bacteria : Iron/Sulphide Ratios in Corrosion by (C. J. P. Spruit and J. N. Wanklyn), 951
Sulphonamides : Identification of, on Paper Chromatograms (Alan E. Steel), 877
  Identification of, by Paper Partition Chromatography (R. Robinson), 512
Sulphur from Sea Water (Prof. Hugh Nicol), 894
Sulphur Sesquioxide · Mode of Decomposition of (A. R. Vasudeva Murthy), 475
Sulphuric Acid (Dilute) : Action of, on Magnetized Iron (Prof. G. Wagner and F. Blaha), 74
Summer School on Relaxation Methods (Imperial College of Science and Technology), 236
Summer School on the Technology of Synthetic Resin Adhesives (Aero Research, Ltd.), 236
Sun : Absence of Hydrogen Radiation of Wave-length 21 cm in the (C. de Jager, Prof. M. Minnaert and C. A. Muller), 391
Sun's General Magnetic Field : The Impossibility of Determining the, by Zeeman Effect Measurements (Prof. H. Alfvén), 1036
Sun and Moon : Blue (Dr. William Paul and Prof. R. V. Jones), 545, 554 ; (R. R. Wilson), 545 ; (G. F. Lothian), 1086
Sunspots . Intensity Variation in (Dr. R. Ananthakrishnan), 291
Superconductive Electrodynamics, *review* by Dr. K. Mendelssohn, 670
Superconductivity Theoretical Aspects of—Crystal Structure and Superconductivity (Prof. H. Fröhlich), 280 ; Superconductivity and Effective Mass of Electrons (Prof. H. Fröhlich), 280 ; Specific Heat of Metals at Low Temperatures (M. J. Buckingham), 281
Superconductivity of Lead Isotopes (Mrs. Marianne Olsen), 245
Supercooled Ionic Melts : Discontinuities in (Dr. N. N. Greenwood and R. L. Martin), 344
Superfluids (Fritz London), Vol. I, Macroscopic Theory of Superconductivity, *review* by Dr. K. Mendelssohn, 670

TITLE INDEX

uperposition Effects in Multiple-Beam Interference Fringes (Audrey M. Glauert), 861
urface Layers of Human Skin and in Finger Nails : Occurrence of Thin Membranes in the (Gösta Lagermalm, Bo Philip and Joel Lindberg), 1080
urface Tension of Liquid Metals (Dr. R. A. Weale), 343 ; (Dr. S. W. Smith), 343
urface Viscometer : A New (W. E. Ewers and R. A. Sack), 964
urfaces : The Rheology of Films and (British Society of Rheology and the Local Section of the Chemical Society Conference on, at University College, Exeter), 369, 945
urgically induced Splenogenic Anaemia in the Rabbit (Kurt I. Altman, Robert N. Watman and Kurt Salomon), 827
urveys of Under-developed Areas (British Association Inter-Section Discussion on), 585
wayback Symptoms in Lambs : Prevention of, by administration of Copper Sulphate to the Pregnant Ewe (Dr. George Dunlop), 728
weden : Forest Research in, 777
wedish Deep-Sea Expedition 1947–48 : International Co-operation in the Analyses of the Deep-Sea Cores collected by the (C. D. Over), 148
wifts in Summer : Movement of (T. H. Hawkins), 157
witzerland : Industrial Research in (Prof. Ronald S. Edwards and Charles La Roche), *review* by R. Brightman, 398
  Technological Research in, *review* by R. Brightman, 398
ynartetic Acceleration and Synartetic Ions. Wagner Changes, (F. Brown, Prof. E. D. Hughes, Prof. C. K. Ingold and J. F. Smith), 65
ynartetic Ions : Wagner Changes, Synartetic Acceleration and (F. Brown, Prof. E. D. Hughes, Prof. C. K. Ingold and J. F. Smith), 65
yntheses : Inorganic (edited by Ludwig F. Audrieth), Vol. 3, *review* by A. J. E. W., 399
  Organic (edited by Arthur C. Cope), Vol. 30, 1950, *review* by Prof. John Read, 928
ynthesis of Carbon-labelled Benzene : A Convenient (H. S. Turner), 73
ynthesis of Cortisone from Reichstein's Compound *D* : Cortical Hormones from *allo*Steroids— (Dr. G. Rosenkranz, Dr. Carl Djerassi, R. Yashin and J. Pataki), 28
ynthesis of 2-Methyl-3 : 4-Benzphenanthrene : A Novel (Dr. S. M. Mukherji and P. N. Rao), 1041
Synthesis of Polyacetylenic Compounds (Prof. E. R. H. Jones, Dr. M. C. Whiting, Dr. J. B. Armitage, Dr. C. L. Cook and Dr. N. N. Entwistle), 900
Synthesis of Protein and Nucleic Acids in the Liver : Effect of Vitamin B_{12} on the (M. R. Sahasrabudhe and M. V. Lakshminarayan Rao), 605
Synthesis of *p*-Terphenyl and its Derivatives. A New (B. K. Ganguly and Dr. S. M. Mukherji), 1003
Synthetic Polypeptides and Gelatin : Optical Rotation and Chain Folding in (Dr. Conmar Robinson and M. J. Bott), 325
Synthetic Polypeptides and Proteins : Structure of (Dr. C. H. Bamford and W. E. Hanby), 340
Synthetic Protein Analogues. Monolayers of (Toshizo Isemura, Kozo Hamaguchi, Dr. Hisaya Tani, Junzo Noguchi and Heimei Yuki), 165
Synthetic Resin Adhesives : Technology of (Aero Research, Ltd., Summer School on), 236
Synthetische Methoden der organischen Chemie (W. Theilheimer), Repertorium 3, *review*, 262
Systematics : More New, *review* by Dr. W. B. Turrill, 1096
Systematik der höheren Pflanzen : Grundlagen und Methoden einer Erneuerung der (Dr. Franz Buxbaum), *review* by Dr. W. B. Turrill, 1096

TABOO: Totem and (Sigmund Freud), authorized translation by James Strachey, *review* by Prof. Raymond Firth, 888
Tapetum (Cat's): Spectral Reflexion Factor of the (G. Gunter, H. G. W. Harding and Dr. W. S. Stiles), 293
Tarnish and Corrosion of Silver and Bronze, 639
Taste and Smell : Localization of Gustatory and Olfactory Enzymes in the Rabbit, and the Problems of (A. F. Baradi and Dr. G. H. Bourne), 977
Taxonomic Proposal : Lectotypes in Mycology, a (E. J. H. Corner), 1031
Taxonomic Theory since 1851 : The Development of (J. S. L. Gilmour), 400 ; *erratum*, 500
Taxonomy of Lichens : Biochemistry in the (I. Mackenzie Lamb), 38
Taxonomy of *Penicillium*, *review* by G. Smith, 261
Taylor (George, of Australia) Gold Medal of the Royal Aeronautical Society awarded to R. E. Bishop, 498
Technical Assistance : United Nations Work and Programmes for, 544
Technical Colleges : Foremanship Training in (British Institute of Management Report on), 367
Technical Material for Publication : Preparing (University of Illinois Engineering Experiment Station, Circular Series No. 62), 857
Technical Writing on Radio : Awards for (Radio Industry Council), 858
Technological Research in Switzerland, *review* by R. Brightman, 398
Technologist : The Training of a (Prof. F. H. Garner), 724
Technology : Humanism and, *review* by Colonel H. D. Anthony, 590
  Leadership, Education and, 753
Technology in the Past Hundred Years : The British Contribution to Science and (H.R.H. the Duke of Edinburgh), 219
Technology in India and South-east Asia : History of Science and (Dr. Joseph Needham), 64, 1048 ; (Dr. S. L. Hora), 1047
Technology of Defects in Paints, *review* by Dr. A. E. A. Werner, 715
Technology of Synthetic Resin Adhesives (Aero Research, Ltd., Summer School on), 236
Technology and Chemistry of Alkaloids (Frank E. Hamerslag), *review*, 311
Tektites : Age of (Hans E. Suess, Richard J. Hayden and Mark G. Inghram), 432
Television : British Contribution to (Radio Section of the Institution of Electrical Engineers Convention on), 641
Television in the North of England, 680
Television-Cable System : The London–Birmingham (T. Kilvington, F. J. M. Laver and H. Stanesby), 1034
Tellurium Film : A Photo-conductive Effect in (W. T. Blackband), 704
Temperature: Effect of, on the R_F Values of the Amino-acids during Paper Chromatography with Solvents completely Miscible with Water (D. P. Burma), 565
Temperature (Low) : Ferromagnetic Resonance Absorption and a New Transition in $NiOFe_2O_3$ at (Prof. Toshihiko Okamura), 162
Temperature Characteristics of the Microflora of Central African Soils (H. Laudelout and J. Meyer), 791
Temperature Dependency of Half Line-Width in Ferrite (Prof. Toshihiko Okamura and Yoshiharu Torizuka), 872
Temperatures (Different) : Growth Hormones of Rice Grains Germinated at (Prof. S. M. Sircar and T. M. Das), 382
Temperatures (Elevated) : Properties of Metals at (George V. Smith), *review* by Prof. F. C. Thompson, 49
Temperatures (High Environmental) : Heat Tolerance of European Breeds of Cattle exposed to (J. Dobinson), 882
Temperatures (High and Low) : Mechanical Properties of Metals at, *review* by Prof. F. C. Thompson, 49
Temperatures (Low) : The Measurement of (C. T. Linder), 411
  The Properties of Metallic Materials at (P. Litherland Teed), *review* by Prof. F. C. Thompson, 49
Tension : Effect of, on Water Absorption by Hair (Dr. L. R. G. Treloar), 521
Terminology for Use in Lactational Physiology (Dr. A. T. Cowie, Dr. S. J. Folley, B. A. Cross, Dr. G. W. Harris, Dora Jacobsohn and K. C. Richardson), 421
Termites : The Protection of Buildings and Timber against (W. D. MacGregor and R. C. Fisher), 102
Terms used in the Plastics Industry : Glossary of (British Standard 1755 : 1951), 983
p-Terphenyl : A New Synthesis of, and its Derivatives (B. K. Ganguly and Dr. S. M. Mukherji), 1003
Terramycin and Chloromycetin : Action of, on Cholera Vibrio in Mice (Dr. E. Olejnik and S. Davidovitch), 654
Territorial Behaviour in Birds (R. W. Nero and J. T. Emlen, Jun.), 1068
Tetrabromothiophene from 2-Bromothiophene by means of Sodium Acetylide in Liquid Ammonia (A. Vaitiekunas and Prof. F. F. Nord), 875
Tetrahydroharman : Isolation of, from *Petalostyles labicheoides* (Dr. G. M. Badger and A. F. Beecham), 517
2 : 3 : 4 . 6-Tetramethylpyridine from Coal Tar : Isolation of (H. B. Nisbet and A. M. Pryde), 832
Tetraphosphate Ion : Chromatographic Evidence for the (Dr. A. E. R. Westman and A. E. Scott), 740
Tetronic Acid Derivatives : Chlorophyll Inhibition and Growth Regulation by several (J. Alamercery, Dr. C. L. Hamner and M. Latus), 85
Textile Chemistry at Manchester, 17
Textile Research Fellowships (Commonwealth Scientific and Industrial Research Organization), 683
Theism and the Individual, *review* by F. I. G. Rawlins, 178
Theoretical Aspects of Superconductivity—Crystal Structure and Superconductivity (Prof. H. Fröhlich), 280 ; Superconductivity and Effective Mass of Electrons (Prof. H. Fröhlich), 280 ; Specific Heat of Metals at Low Temperatures (M. J. Buckingham), 281
Theoretical Determination of Electron Density in Organic Molecules (Dr. O. Klement), 162 ; (Prof. C. A. Coulson, P. W. Higgs and N. H. March), 1039
Théorie des fonctions : Lecons sur la (Émile Borel), quatrième édition, *review*, 658
Theories of Aether and Electricity : A History of the (Sir Edmund Whittaker), revised edition, *review* by Prof. W. H. McCrea, 1053
Theories of the Visual Threshold, *review* by Dr. W. S. Stiles, 758
Théories photochimiques classiques et quantiques de la vision et l'inhibition nerveuse en vision liminaire (Ernest Baumgardt), *review* by Dr. W. S. Stiles, 758
Theory : Evolutionary, *review* by Prof. Sewall Wright, 351
  Measure (Prof. Paul R. Halmos), *review* by Prof. H. T. H. Piaggio, 260
Theory of Convergence : Adaptation in Rodent Moles and Insectivorous Moles, and the (Dr. G. Eloff), 1001
Theory of Functions, *review* by Prof. H. T. H. Piaggio, 216
Theory of Magnetic Storms and Auroras (Prof. Sydney Chapman), 86
Theory of Nonlinear Oscillations : Contributions to the (S. P. Diliberto, L. L. Rauch, F. H. Brownell, M. L. Cartwright, J. G. Wendel, C. E. Langenhop, A. B. Farnell, W. Wasow, edited by S. Lefschetz), *review* by Prof. H. T. H. Piaggio, 49
Theory of Probability and Statistics : Introduction to the (Prof. Niels Arley and Prof. K. Rander Buch), *review* by David G. Kendall, 217
Theory of Solutions : Statistical (Dr. A. B. D. Cassie), 382
Thermal Conductivity of Dielectric Crystals—The 'Umklapp' Process (Dr. R. Berman, Prof. F. E. Simon and Dr. J. Wilks), 277
Thermal Conductivity of Human Fat and Muscle (Dr. H. Stafford Hatfield and Dr. L. G. C. Pugh), 918
Thermodynamics of Ferrous Sulphide (C. B. Alcock and Dr. F. D. Richardson), 661
Thiocyanate Ions in Soil : Microbiological Oxidation of Ammonium and (Dr. H. Gleen), 117
Thiouracil : Inhibition of the Biosynthesis of Tobacco Mosaic Virus by (Dr. Barry Commoner and Frank Mercer), 113
Thomas–Fermi–Dirac Equation : Solution of the (Prof. P. Gombás and R. Gáspár), 122
Thought : Faster than—the Ferranti Nimrod Digital Computer (Ferranti, Ltd.), 70
  Freedom of Speech and, 305
Thought of C. S. Peirce : The (Prof. Thomas A. Goudge), *review* by F. I. G. Rawlins, 311
Thurlow Award for 1950 of the Institute of Navigation of the United States, given to Dr. E. G. Bowen, 144
Thyratrons : The Industrial Applications of Gasfilled Triodes (R. C. Walker), *review* by Dr. U. W. Arndt, 50
Thyroxine Therapy in Male Infertility (Dr. M. Maqsood), 466
Ticks of South Africa (Gertrud Theiler), 589
Tidal Streams : Influences of, on Oceanographic and Climatic Conditions in the Sea as exemplified by the English Channel (Dr. G. Dietrich), 8
Timber : The Protection of Buildings and, against Termites (W. D. MacGregor and R. C. Fisher), 102
Timber in Great Britain : Volume Tables for Estimating, 111
Timbers (Australian) : Suitability of, for Veneers (A. J. Watson and H. G. Higgins), 640
Timbers (Kenya) : Catalogue of (S. H. Wimbush), 813

Time and Climate, *review* by Dr. E. C. Bullard, 48
Tissue Sections (Ultra-Thin) : A Method for making, for Electron Microscopy at High Resolution (Fritiof Sjostrand), 646
Tobacco Mosaic Virus : Inhibition of the Biosynthesis of, by Thiouracil (Dr. Barry Commoner and Frank Mercer), 113
Tone Sensation produced by Repetitive Trains of Auditory 'Click' Stimuli (W. T. Catton), 882
Tonerde und Aluminium, Ergebnisse und Erfahrungen aus der Betriebspraxis 1920–1950 (Dr. Wilhelm Fulda und Dr. Hans Ginsberg), Teil 1, *review*, 397
Tooth (Human) : Transamination in the (W. G. Armstrong and H. F. Atkinson), 695
Toroidal Geiger Counter : A (C. P. Haigh), 246
Totem and Taboo (Sigmund Freud), authorized translation by James Strachey, *review* by Prof. Raymond Firth, 888
Tow-net : A High-speed (D. T. Gauld and T. B. Bagenal), 523
Toxicity : Low, of the Diphtherial Culture Filtrate and its relation to the Absence of Tyrosine in the Medium (Masahiko Yoneda), 879
Toxicity of Copper in Solution to the Stone-loach (F. J. Mackereth and W. J. P. Smyly), 1130
Trace Elements in Plants and Animals (Prof. Walter Stiles), second edition, *review* by K. W., 486
Tracer Technique : Solid Phase Determinations in the System Aluminium Sulphate/Sulphuric Acid/Water using (Duncan Taylor and Richard Scott), 520
Tracks of Protons and Mesons in Photographic Emulsions : Density of (Torsten Gustafson), 377
Trade Barriers to Knowledge (Unesco), 437
Transaminases in *Neurospora crassa* (Dr. J. R. S. Fincham), 957
Transamination in the Human Tooth (W. G. Armstrong and H. F. Atkinson), 695
Transamination to Pyruvate and some other *α*-Keto-acids (E. V. Rowsell), 104
Transatlantic Radio : Anniversary of (Dr. R. L. Smith-Rose), 980
Transformation Calculus and Electrical Transients (Prof. Stanford Goldman), *review*, 577
Transition in Carbon Tetrabromide : Nature of the (Dr. J. G. Marshall, Dr. K. R. Hart and L. A. K. Staveley), 519
Transition Effect of the Star-producing Radiation (L. Tomášková), 1005
Translations (Scientific) : Commonwealth Index of, 235
Transmission of Natural and Synthetic Mica in the Ultra-Violet (P. Popper), 1119
Transplantation of Mouse Eggs (R. A. Beatty), 995
Trematodes and Cestodes: Egg-Shell Formation in, as demonstrated by the Methyl or Malachite Green Techniques (Dr. J. D. Smyth), 322
Tribal Art : Science and (William Fagg), 1099
Tricarboxylic Acid in Liver : A Phosphate Ester of a (S. Rapoport and Robert H. Wagner), 295
Trichomonas foetus : Hydrogen Evolution by (Suzuoki-Ziro and Suzuoki-Tuneko), 610
Trichothecin : 'Double-Action' of, and its Production in Soil (D. G. Hessayon), 998
Trifluoroacetic Anhydride and Oxy-Acids : Properties and Reactions of Mixtures of (Dr. E. J. Bourne, Dr. J. E. B. Randles, Dr. J. C. Tatlow and Dr. J. M. Tedder), 942
Triodes (Gasfilled) : The Industrial Applications of (R. C. Walker), *review* by Dr. U. W. Arndt, 50
Tris-Acetylacetone Cobalt III : Preparation of the Optical Forms of (Dr. F. P. Dwyer and Miss E. C. Gyarfas), 29
Trithiocarbonate Derivatives of Carbohydrates : Some (G. P. McSweeney and Prof. L. F. Wiggins), 874
Tritiobutane in the Geiger Counter : Estimation of Radioactive Hydrogen as (Dr. R. F. Glascock), 121
Tritium . Stimulation by Insulin of *in vitro* Fat Synthesis by Mammary Tissue studied with Carbon-14 and (Judith H. Balmain, Dr S. J. Folley and Dr. R. F. Glascock), 1083
Tropical Animal Nutrition, *review* by Dr. John Hammond, 440
Tropics : Termites and Building in the, 102
Trypsin and Plasmin: Quaternary Detergents and the Activity of (Dr. Tage Astrup and Norma Alkjaersig), 565
Tryptophan : Intermediary Metabolism of (Dr. C. E. Dalgliesh, Dr. W. E. Knox and Dr. A. Neuberger), 20
Tryptophane : Destruction of Dinitrophenyl Amino-Acids by (Adrienne R. Thompson), 390
Tubercle Bacillus (Bovine) : Nature and Infectivity of Granular Forms of the (Dr. E. M. Brieger, Dr. J. A. R. Miles, Dr. V. E. Cosslett and R. W. Horne), 96
Tuberculin : Sensitivity to (Dr. C. N. D. Cruickshank), 206
Tuberculosis : Chemotherapy of (Medical Research Council of Ireland Symposium on), 539
  Dorothy Temple Cross Research Travelling Fellowships in (Medical Research Council Awards), 189
Turkey : Medical Education in (Prof. F. Nafiz Uzluk), 821
Turner as a Weather Painter, a Centenary Appreciation (L. C. W. Bonacina), 1105
Turnover of Potassium Ions in Kidney Slices : Rapid Rate of (Dr. R. E. Davies and Dr. A. W. Galston), 700
Turnover Rates of Radioactive Isotopes : Errors in Determination of Specific Activity and (Prof. A. H. Ennor and H. Rosenberg), 199
Twentieth Century : Scientific Thought in the (edited by Prof. A. E. Heath), *review* by W. L. Sumner, 214
Tyrosinase and Polyphenoloxidase—the Role of Metallic Ions in Melanogenesis (Dr. Denis Kertész), 697
Tyrosine in the Medium : Low Toxicity of the Diphtherial Culture Filtrate and its relation to the Absence of (Masahiko Yoneda), 879

UGANDA : Forest Policy in (Prof. E. P. Stebbing), 507
Ultra-Sound Waves : Inhibition of the Hypophysis of the Guinea Pig by (Prof. V. H. Cicardo, Dr. A. A. Cappellino and Dr. E. Del Conte), 169
Ultrasonic Irradiation : Effects of, on the Coagulation of Celluloid Solutions (Viscose), (Dr. V. Tomberg), 292
Ultrasonics (Dr. P. Vigoureux), *review* by E. G. R., 1016
  International Conference on (Royal Flemish Academy and Unesco), 106
Ultrasonics in Fluids (Dr. E. G. Richardson), 106
Ultra-Thin Tissue Sections for Electron Microscopy at High Resolution : A Method for making (Fritiof Sjostrand), 646
Ultra-Violet : Transmission of Natural Synthetic Mica in the (P. Popper), 1119
Ultra-Violet Absorption of Reduced Phosphomolybdate (Dr. R. Consden and Winifred M. Stanier), 298
Ultra-Violet Absorption Spectra of Gallium and Indium Monofluorides (D. Welti and R. F. Barrow), 161
'Umklapp' Process : Thermal Conductivity of Dielectric Crystals—The (Dr. R. Berman, Prof. F. E. Simon and Dr. J. Wilks), 277
Under-Developed Areas : Surveys of (British Association Inter-Section Discussion on), 585
Undulatory Propulsion in Small Organisms (Prof. J. Gray), 929
Unesco, Peace in the Minds of Men (Theodore Besterman), 797
Unicam Spectrophotometer : Rotatory Dispersion Measurements with a (Dr. Stotherd Mitchell and James Veitch), 661
Unions : The Future of the (Nationalized Industry Series, 8), 1094
United Nations Work and Programmes for Technical Assistance, 544
United States · Manpower Shortage in the (Dr. M. H. Trytten), 725
  Scientific Workers and Defence Research in the, 857
United States of America : The Pharmacopeia of the (the United States Pharmacopeia), fourteenth revision (U.S.P. 14) and the first U.S.P. 14 Supplement, *review* by J. H. G., 577
United States (Eastern) : The Stipitate Hydnums of the (Prof. William Chambers Coker and Alma Holland Beers), *review* by E. J. H. Corner, 1015
Unity and Complexity, *review* by F. I. G. Rawlins, 574
l'Univers (Canon Georges Lemaitre), *review* by Prof. T. G. Cowling, 259
Universe : The Beginning of the, *review* by Prof. T. G. Cowling, 259
Universities : Functions of the, 89
  Leadership Training in the (Sir Walter Moberly), 769
  English, and Adult Education (S. G. Raybould), 886, 923

only a guide and friend for the undergraduate, but it can also remain a stimulating companion in mature experience.

It is rather remarkable, but no doubt deliberate, that the conventional vector diagram of A.C. circuit theory is not utilized at all in the work even to illustrate skin effect phenomena to which this representation is well adapted. At least one group of minor misprints has been transmitted from the first edition, namely, the omission of '*dx*' from several of the equations on p. 241. JAMES GREIG

SPECTROCHEMICAL ANALYSIS

Metal Spectroscopy

By F. Twyman. Pp. ix+569. (London: Charles Griffin and Co., Ltd., 1951.) 50*s*. net.

THE development of spectroscopy proceeds with ever-increasing pace: from the discovery of the spectrum by Newton in 1672, the use of flame spectra to distinguish between lithium and strontium by Talbot in 1834, the spectroscopic discovery of cæsium and rubidium by Kirchhoff and Bunsen in 1861, and the first serious attempts at spectrochemical analysis by Hartley and de Gramont at the turn of the century, to the present, when the all-pervading science of electronics is being applied to spectrochemistry. The historical side is most readably presented in the opening chapter, but the importance of this book is in its complete and up-to date treatment of recent developments in a rapidly expanding field. These rapid developments have led to the replacement of Mr. Twyman's "Spectrochemical Analysis of Metals and Alloys", which was written during the difficult early war years and published in 1941.

Mr. Twyman has been outstanding in the development of spectroscopic equipment and technique, and his experience in the field extends back half a century. Although he has been so closely associated with Messrs. Adam Hilger, Ltd., this book is not tied to the instruments of this firm, and the important contributions to spectrochemistry from Germany, the United States and other countries are given full weight, and the instruments of other firms are fully covered.

Practically every aspect of spectrochemical analysis is dealt with in more than five hundred closely written pages. There is a short chapter dealing with the fundamental principles of the theory of atomic spectra (the unusual notation of writing the upper state of a transition to the left may be noted), but thereafter the emphasis is on the instruments and experimental technique; this practical aspect may be illustrated by the section on shielding of sparks to prevent radio interference. Chapters on light sources, electrodes, X-ray spectrochemistry, and the present trend of developments are contributed respectively by A. Walsh, M. Millbourn, F. Brech and F. Holmes.

For the analysis of metals, especially in routine testing of numerous samples, or in detecting trace elements in soils, spectroscopic analysis obviously has many advantages; but it is not only for metals that it can be used, and the book also covers analysis of gases and of some non-metals such as sulphur, selenium, carbon and boron. Colorimetry and spectrophotometry, microphotometers, the infra-red region, and the use of spectrochemical analysis combined with chromatography are also dealt with. An interesting suggestion is the possible extension to shorter wave-lengths, perhaps by the use of fluorite prisms, to reach more sensitive lines such as those of sulphur and selenium. Types of instruments are compared, and, while Mr. Twyman admits that gratings have some real advantages, the limitations due to overlapping orders, astigmatism and ghosts are pointed out.

This book is by far the most comprehensive and authoritative treatment of the subject available, and is strongly recommended. If there is a weakness it probably lies in the presentation: the table of contents only gives chapter headings, and as these are in general terms it is not always easy to find the section of interest—thus Raman spectra come under "Electronic Methods". There is a good bibliography, and the book is well produced. A. G. GAYDON

RHODODENDRON LEAVES

The Rhododendron Leaf

A Study of the Epidermal Appendages. By Dr. John Macqueen Cowan. Pp. xi+120+18 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1950.) 21*s*. net.

THE study of the rhododendrons has long been pursued in the Royal Botanic Gardens, Edinburgh, blessed by an ever growing wealth of living plants and by unswerving interest in taxonomy. Throughout this time a widespread view has come that, while specific status or generic rank may well be proved by form and stature of papillæ or of hairs or scales retained on mature leaves, in other respects the forms and groupings of the hairs or scales may point to true relationships, the seekers of which have hitherto all assumed that species bearing scaly leaves are of distinct descent from all those that have hairy leaves or lack such dermal organs.

This broad assumed distinction was employed throughout "The Species of Rhododendron" (1930), both in the seriation of the plants described and often, too, as if it can denote for new-found or for doubtful plants some special series which already hold their nearer kith and kin. Although this standard book allowed that certain series then proposed embrace confusing plant assemblages, its plan again implied that plants with hairs or scales are rightly viewed as of distinct descent.

The present handsome book relates how, though so often contrasting in their forms and states, the hairs and scales which many species bear alike arise from single superficial cells, and how their products must be held of unit kind, though built on diverse plans. Since it shows, too, how dermal organs borne by hybrid plants may stand in all respects between hairs and scales, how certain species vary much in types of hair-display, and how, in others, hairs and scales are formed on every leaf, it seems the old assumption must be set aside until it is known what hair- and scale-formation mean to living plants themselves.

No matter how these findings bear on taxonomic problems, this book has interest far beyond the field of systematics or that of horticulture. It first relates how needful lines of study grew from those already traced, and how through simple technique knowledge came of many trichome-forms which had not always drawn comment or were misunderstood. Each one of these is then described and faithfully portrayed before it is shown what founded species-series are still justified, and which must be revised.

Throughout its length, this book impresses one by the author's sense of plants as living things, each posing many problems still but slightly grasped and which must duly be essayed if one should hope to picture near relationships.

Although the major chapters brim with novel observations, they rather seek to urge research than to suggest conclusions. Perhaps the final chapter will serve the most to quicken new inquiry; for, vividly, it turns the mind from plants in cultivation to an understanding of, in part, their fitness to their native habitats and their sustained survival.

This simply written book reflects a long and arduous effort. Its illustration merits special praise, as does its composition. J. McLean Thompson

A POPULAR NATURE STUDY

Nature through the Year

By Frances Pitt. Pp. vii+300. (London: Macmillan and Co., Ltd., 1951.) 18s. net.

FRANCES PITT'S literary excursions in natural history are now so well known that there can be few with love of Nature who have not met her in person or print. In her latest work this popular writer presents a colourful account of natural events throughout the year. As always, the book is written in a delightful narrative style which is accompanied by evidence of acute powers of observation stemming from keen interest in and love of living things.

In some ways the title of the book is a misnomer. Although other aspects of Nature are referred to, Miss Pitt is mainly concerned with birds and mammals, and these, not unexpectedly, sometimes include those well-loved pets with which the author has had long acquaintance and studied so carefully. The book, in fact, would serve as an admirable supplement to the popular "In Britain" series by the same publishers, particularly if these in turn were strengthened by a work dealing with insects in Britain.

The arrangement of the book is on a weekly basis. Beginning on January 1 and continuing for each successive week throughout the year, the author has recorded significant impressions which she has observed, and has used these as starting points for gentle dissertations on biological principles or practices. An encounter with a hare, for example, leads naturally to discourse about animal camouflage, while genetic principles are introduced after a mild detective story in which a Manx cat is the chief suspect.

In these voyagings Miss Pitt does not hesitate to roam wherever fancy takes her, and one of her weekly episodes begins with an account of a squirrel's reaction to the sting of a wasp, continues with the description of a squirrel which had "bilious" attacks which may have been brought on by eating Brazil nuts, and finishes with possible explanations of old legends about spectral horsemen and ghostly hounds running equally ghostly quarry through the night; these vagaries do not detract from the charm of the book. Nor do some minor errors, although, when another edition of the book is called for, Miss Pitt should not—on p. 73—begin a sentence by saying that she "could not give a *definite* answer", and end it with "the reason is *undoubtedly* one of light and lighting". So, too, with other parts of the text which appear to have been hastily written and have become so loosely constructed that, as on p. 289, the author has exposed herself to the charge of anthropomorphism.

The book is generously provided with black-and-white illustrations, the photographs for which were taken by Miss Pitt; the majority of these are clear but a few are well below the standard associated with the publishers.

In a world where the search for truth has become so objectively impersonal that much present-day writing lacks the warmth and colour of human emotion, Miss Pitt's book makes refreshing and interesting reading mainly because the author has nowhere tried to conceal her feelings and idiosyncrasies.

Besides British readers, "Nature through the Year" would be an admirable guide for visitors from overseas who have come to examine Britain as she really is in Festival year. T. H. Hawkins

ATOMIC REMINISCENCES

New Atoms

Progress and some Memories. By Otto Hahn. A collection of Papers, edited by Dr. W. Gaade. Pp. 184. (New York and Amsterdam: Elsevier Publishing Co., Inc.; London: Cleaver-Hume Press, Ltd., 1950.) 12s. 6d.

THOUGH there has been a number of books purporting to expound the scientific facts about 'atomic energy' to the non-technical reader, this little volume should hold its own. It is a collection of four lectures, each complete in itself; hence some overlap is unavoidable. The first is the Nobel Lecture given by the author in 1946, and is an account of the work which led up to the discovery of nuclear fission. The occasions on which the other three lectures are given are not stated; the second is largely physical, centred around the nuclear chain reaction which followed soon after the discovery of fission. In the third, the author is at home again in his beloved chemistry, zestfully describing the new elements (no less than ten) which recent nuclear research (not all of it directly connected with fission) has given the chemists to play with. The last brings reminiscences of the early years of radioactivity; less technical and often humorous, it paints a lively canvas of those heroic days when radium was new and anything might happen.

The style is very straightforward, indeed rather subtle in its simplicity. It avoids the long-winded explanations which are apt to stress rather than resolve difficulties, and it is also refreshingly free from that hectic verbiage by which some popular writers lash the flagging attention of their jaded readers. Much of the information given, particularly in the third lecture, is fairly technical; but it is always presented in simple language. Perhaps the most valuable feature is the sense of historical unity, connecting early radioactivity and modern atomic energy, a unity of which the author is a living symbol and which he succeeds very well in communicating.

On the whole, this is a most likeable little book, written by a man who took a leading part in the development of radioactivity and who enjoys telling us about his work and the scientific scenery in which it took place. The translation is good; a few minor slips are easily spotted and do no harm.

O. R. Frisch

Solvents

By Dr. Thos. H. Durrans. (Monographs on Applied Chemistry, Vol. 4.) Sixth edition, revised and enlarged. Pp. xv+242. (London: Chapman and Hall, Ltd., 1950.) 21*s.* net.

THIS well-known and useful monograph was first published in 1930 to provide a scientific exposition of the technical application of solvents, more particularly in connexion with the cellulose-lacquer industry. The considerable advances in the production of solvents and plasticizers during the past twenty years made it necessary to subject the book to frequent revision if it was to retain its usefulness as an up-to-date manual, and it has now reached its sixth edition, which fully maintains the standard of its predecessors.

The general arrangement of the previous editions has been retained, the first part of the book discussing the more theoretical aspects of the subject, and the second part dealing with the characteristics and uses of individual solvents and plasticizers. The chapter on toxicity has undergone considerable revision and extension in the light of recent discoveries and opinions. Appendixes give a very useful and comprehensive list of trade names with probable compositions (now extended to some 576 entries), solubility tables and plasticizer proportions. The solubility tables give information on the solubility of twenty-seven different substances, such as cellulose acetate, rubber, gums, oils, etc., in more than a hundred different solvents.

The present edition may be accepted as containing the most recent information and experience in its particular field, and can be recommended with confidence to all who have to deal with solvents and plasticizers. E. H. NURSE

British Journal of Applied Physics

Edited by Dr. H. R. Lang. Vol. 1, 1950. Pp. iv+340. (London: Institute of Physics, 1950.) £4.

THE monthly periodical, *British Journal of Applied Physics*, was launched in January 1950 by the Institute of Physics in order to provide the steadily increasing number of physicists employed in industry with a medium for the publication of new applications of physics, especially in industry, and for the description of developments of older applications. The completion of Vol. 1 provides a welcome opportunity to direct attention again to the excellence of the *Journal*, and to commend the editor, Dr. H. R. Lang, and the advisory committee for their continued meritorious efforts.

All but one of the twelve monthly issues have contained one or more special articles or special reports, in addition to the several original contributions, reviews of new books and notes and comments. Scientific education, environmental warmth and human comfort, the 1948 revision of the international temperature scale, and electrical conduction in glass are the subjects of the four special articles, and the special reports consist of summaries of the proceedings of various conferences and discussions held by branches of the Institute during the past two years. It is impossible to summarize adequately the various original contributions. They range over a wide field covering electronics, vacuum technology, photoelasticity, rheology and glass technology. Only one of the contributions, "An Electromagnetic Problem", by Dr. G. F. C. Searle (p. 268), seems to be out of place in a periodical devoted solely to applied physics, but the editor may be excused for this apparent lapse because the problem discussed is of considerable fundamental interest. It arose when preparations for the celebration of the centenary of Heaviside's birth reminded that veteran of experimental physics, Dr. Searle, that, in 1916, he sent an electromagnetic problem to Heaviside for solution but which, apparently, Heaviside either could not solve or merely ignored. The original problem presents great mathematical difficulties; but, in his article, Dr. Searle considers a simplified case which he then proceeds to solve in an elegant manner. Perhaps some physicist may now be prompted to tackle the more difficult problem submitted to Heaviside.

The illustrations, index and binding of this first volume are of a high standard, and the large clear type is particularly welcome. It is to be hoped that proper and adequate support will be forthcoming from members of the Institute, industrial organizations and professional societies for the *Journal* to continue as a medium for bridging the gap between applied physics in the laboratory and its eventual translation into industrial practice. S. WEINTROUB

Light and Sound

By M. Nelkon. Pp. viii+342+2 plates. (London: William Heinemann, Ltd., 1950.) 11*s.* 6*d.*

IN view of the number of text-books of intermediate standard already in existence, the value of yet another is rather doubtful, and it could only be justified by some particularly original treatment and ideas. In this book, however, the treatment throughout is conventional.

University teachers will also note with regret that the author uses the 'real-is-positive' sign convention in light, thus helping further to establish its hold at the school level of teaching. This convention, since it is not easily extended to non-axial points, is of little use in degree courses, and thus a definite cleavage now exists between the teaching of optics in the schools and the universities. The author admits this difficulty, and gives an introduction to the 'new Cartesian' convention in an appendix. Since this convention was recommended in 1934 by a committee appointed by the Physical Society, it is a matter for regret that it is not more widely adopted.

Applied Mycology and Bacteriology

Originally compiled by L. D. Galloway and Dr. R. Burgess. (Modern Chemical Industries Series.) Third edition, revised by L. D. Galloway. Pp. viii+184+8 plates. (London: Leonard Hill, Ltd., 1950.) 12*s.* net.

MANY workers in mycology and bacteriology will already know this book from earlier editions. It is perhaps most valuable as a general introduction to methods of work and to the techniques of handling and control of micro-organisms. Part 1 deals with such questions, and includes several modern contributions. Part 2 is a wide review of the ways in which fungi and bacteria are connected with industry, medicine and food. There is here not sufficient detail for the specialist, who may, nevertheless, be able to glean one or two ideas from other fields of action. The section serves as a very good introduction for the student or laboratory worker, and it makes interesting reading. Mr. L. D. Galloway has considerably re-written the text for this third edition, and the ten illustrations are so good that more would be acceptable. JOHN GRAINGER

INFLUENCES OF TIDAL STREAMS ON OCEANOGRAPHIC AND CLIMATIC CONDITIONS IN THE SEA AS EXEMPLIFIED BY THE ENGLISH CHANNEL

By DR. G. DIETRICH
German Hydrographic Institute, Hamburg

IN so far as a periodically recurring wave process is linked up with friction and eddy viscosity, it can well exercise permanent influences in the sea. In the case of tidal streams, various effects of this kind can be observed. Being closely associated with tidal waves which are very long compared with the depth of the water, the tidal streams reach right down to the bottom of the sea, where they are diminished by frictional influences. From hydrodynamics it is well known that, with increasing vertical change of velocity, the eddy viscosity will be intensified if the stability of the layering of the water remains below a certain critical value. Since, in the sea, this limitation is mostly fulfilled, the density stratification will be diminished in the presence of tidal streams. In the case of low speeds, destruction of the density stratification will be confined to the neighbourhood of the sea bottom; at higher velocities, however, the destruction will be intensified until the tidal streams have succeeded in mixing the whole water column from bottom to surface. The occurrence of strong tidal streams is confined to limited parts of the marginal seas where topography favours the development of high tidal waves. Hence, in this type of area, water masses which are in a considerably differentiated stage of mixing may be found within a short distance from each other; this situation facilitates the comparison of the physical effects.

The English Channel is particularly suited for demonstrating the influences of tidal streams. The velocity of these currents reaches high values in this area, and its distribution is well known from a recent paper by W. Hansen[1] summarizing the observations. In addition, the oceanographical and meteorological factors are supported by an abundant and very diversified mass of observational material. References to the material and methods of elaboration of it have been dealt with in another paper[2].

Fig. 1 shows several oceanographical and climatic factors presented for a line which follows the axis of greatest depths and is more or less coincident with the orthodrome from 48° N., 8° W., to 51° N., 1½° E. This line runs from the continental slope in the Bay of Biscay as far as the Straits of Dover. *B* indicates the topography of the bottom along this line. Some of the factors indicated do not take into consideration the small depression of the Hurd Deep, in order to avoid a one-sided representation. In winter, the whole water column is homogeneous from the surface down to the bottom of the sea, while in summer, in the Bay of Biscay, a characteristic stratification develops. This consists of a homogeneous top layer with high temperatures, and a cool homogeneous subsurface layer. The line *T* indicates the mean depth of the temperature discontinuity between these two layers in August. The temperature difference Δt between these two layers, corresponding to the temperature difference between the surface and the sea bottom, gives an idea of the magnitude of the temperature discontinuity. In the western entrance of the Channel, abreast of Ouessant, the discontinuity layer rises remarkably from a depth of 45 m. to 20 m. and in the same region Δt falls from about 6° to less than 2° C.

This phenomenon demonstrates the immediate effect of the mixing process caused by tidal streams. Fig. 1 shows that the velocity of the tidal streams *V* rises from 1 to 2 sea miles/h. (knots) in the same area. Consequent upon the greater vertical turbulence caused by the increased frictional influences near the bottom, the discontinuity layer is carried off from below and hence, as a whole, becomes shallower and less powerful. Towards the central part of the English Channel the tidal streams increase to such an extent as to cause the summer discontinuity to be completely destroyed. Hence, it is not only in winter, but also in summer, that the central and eastern parts of the Channel are thoroughly mixed from the surface down to the bottom. Owing to the shallow depths in the area extending from the Isle of Wight to Dover, the local falling-off of tidal stream speeds does not suffice for the formation of a summer layering there.

As a result of the mixing process enforced by the tidal streams, the quantity of heat available at the sea surface from the heat balance will be imparted to a far thicker water layer than would be the case if there were no tidal mixing process. The heat balance at the surface being limited, the annual variation of the surface temperature will be damped. The annual mean variation of the surface temperature, $t_{Wh}-t_{Wl}$, which in the latitudes concerned normally rises with approach to the Continent, can be seen from Fig. 1 to show a noteworthy decrease abreast of Ouessant in that the maximum annual temperature t_{Wh} falls and the minimum temperature t_{Wl} rises. At the surface, this damping is imparted to the air temperature and, unlike the conditions in the Bay of Biscay and the eastern Channel, there is observed a decrease in the annual variation $t_{Ah}-t_{Al}$ in the western Channel. In taking the annual variation as a measure of continentality—as is customary in climatology—one arrives at the apparently paradoxical conclusion that the open Bay of Biscay has a greater continentality than the adjacent western Channel. This phenomenon is due to the effect of the mixing process caused by tidal streams.

The damping will be manifested not only in a diminution of the mean annual variation of water and air temperatures but will also reveal itself in the mean retardation of phases of the annual variations. To express this in a more illustrative way, it will become evident in the retardation of the setting-in of the annual maxima P_W and P_A. Because of this, the premature occurrence of the maxima normally found in approaching the Continent is decisively disturbed. In the central Channel abreast of Guernsey, the P_W values are delayed until September 11, the corresponding date in the Bay of Biscay being August 20. The maxima of the air temperatures are much less delayed, namely, by five days. The maximum is retarded until August 17, as compared with August 12 in the western approaches to the Channel. The noticeable increase in the phase difference between the annual variations of water and air temperatures, as shown in Fig. 1, contributes to the development of extraordinary values of temperature gradient in the air layer near the water

////, Annual variation of air temperature in °C.
//////, Annual variation of surface water temperature in °C.

surface. In early summer, at the time of the greatest rise in temperature, the water in the central part of the Channel is considerably cooler than the air, whereas in late autumn, at the time of the greatest fall in temperature, the water is considerably warmer than the air. In consequence, the meteorological conditions essential for the formation of fog and mist are produced in early summer, while, on the other hand, the formation of fog and mist will be rendered more difficult in late autumn. From the observations recorded in Fig. 2, this is impressively confirmed. The lighthouses Les Hanois and Casquets are at open places in the central part of the Channel, Les Hanois west of Guernsey, and Casquets west of Alderney. In order to establish a comparison, reference has been made to the hours of fog at the Seven Stones light-vessel near the Scilly Isles. Unlike the observations in the central part of the Channel, they show an unimportant annual variation. In the Channel there is an unusual abundance of fog in June/July—involving various dangers for shipping—and an extraordinary absence of fog in October/December. This climatic peculiarity of the Channel is seen to be attributable to the influence of the mixing process of the tidal streams.

The effect brought about by the tidal mixing process, however, accounts for a part only of the anomalous conditions. This becomes particularly evident when the annual variation of heat content in the sea is considered. Curve *H* in Fig. 1 indicates the quantity of heat in 10^5 k.cal./m.² stored up from the time of minimum heat content in winter until the time of maximum heat content in summer, and relates to the compensated bottom topography *B* without taking account of the Hurd Deep. In the western part of the English Channel, this curve rises from 3 to 5·5 × 10^5 k.cal./m.², and over most of the Channel it maintains a value of more than 4 × 10^5 k.cal./m.². These values are not confined to the longitudinal direction indicated in the diagram but extend over the major part of the width of the Channel.

That the situation is unusual will become evident when the components of the heat balance are studied. In Fig. 3 their complete annual variation at the western entrance and in the central part of the Channel is represented; the appropriate calculations were based on methods developed by H. U. Sverdrup[3] and F. Albrecht[4]. The expression is $Q_s = Q_r - Q_b - Q_e - Q_s$ (the legend of Fig. 3 explains these symbols). At the western end of the Channel the quantity of heat which is needed to explain the observed course of temperature throughout the water column down to a depth of 140 m. (Q_t) attains a comparatively close approximation to the local heat balance between ocean and atmosphere (Q_s). The differences between Q_t and Q_s may be conditioned by both the horizontal turbulence of heat and the annual variation of the course of the current. In the central Channel, on the other hand, where Q_t refers to 0–80 m., it is considerably greater than Q_s. The paradox thus occurs that the increase in heat content Q_t is greater than permitted by the radiation of the sun and the sky Q_r. Furthermore, a comparison between the two diagrams in Fig. 3 shows that the values of the vertical heat balance Q_s differ markedly between the

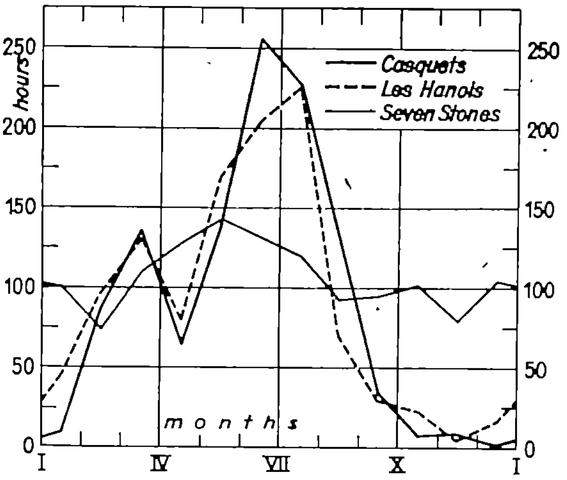

Fig. 2. Mean hours of fog per month in the central part (Casquets and Les Hanois) and in the western entrance (Seven Stones) of the English Channel
(Casquets Lighthouse, 49° 43′ N., 2° 33′ W.; Les Hanois Lighthouse, 49° 26′ N., 2° 45′ W.; Seven Stones Light Vessel, 50° 04′ N., 6° 05′ W.)

two areas. In the central part of the Channel the water receives more heat from the atmosphere in spring and summer than it does at the western end of the Channel, which is, above all, due to the fact that the evaporation heat Q_e remains small. The evaporation heat saved helps to increase Q_s. The unimportant degree of evaporation in the central Channel, as well as the frequent occurrence of fog, are conditioned by the negative difference between water temperature and air temperature. This, as has already been shown, is closely related to the mixing process of the tidal streams. These high values of Q_s cannot, however, sufficiently explain the observed variation of temperature as shown by Q_t; also, the horizontal eddy conductivity of heat is of little avail in this connexion. The horizontal temperature differences remain unimportant, and there are no extensive areas of shallow water as in the Irish Sea. There the shallows contribute very warm water in summer and cool water in winter by way of a horizontal eddy conductivity; in so doing they further the heat exchange in the Irish Sea; as has been shown by K. F. Bowden[5].

The combined effect of water balance and tidal mixing in the Channel is expected to help greatly in unveiling the causes of the anomalous value Q_t in Fig. 3, and of curve H in Fig. 1. From numerous current observations by J. N. Carruthers[6], it is well known that a current flows in a west–easterly direction through the upper layers of the Channel. Yet only a small proportion of the water entering the Channel passes the Straits of Dover; the major portion of it leaves again at the western end. Observations made by J. N. Carruthers[7] and H. W. Harvey[8] with a system of drift bottles on the sea bottom support these views. The arrows in Fig. 1 show this circulation system.

In winter, this type of water balance does not exert any essential influence on the heat balance. The water is then isothermal from the surface down to the bottom, and the inflowing water has equal or similar temperatures to the outflowing water. Hence the amount of heat conveyed into the Channel approximates to that carried out of it. In summer, however, the very warm water of the surface layer flowing into the Channel from the Bay of Biscay is mixed by strong tidal streams with the whole water column. The relatively cool mixed water which flows back again out of the Channel carries less heat with it than was carried in by the inflowing water. As a result, there occurs a horizontal current of heat with an annual period that is effective only in spring and summer, when there exists a thermal layering outside the western entrance of the Channel. This heat current provides the Channel with approximately 2×10^{18} k.cal., which sufficiently explains the anomalies of H and Q_t.

It need scarcely be said that this combined effect of the water balance and tidal mixing process also plays a part in the oceanographical and meteorological factors mentioned at the beginning of this article, but it is difficult to make a quantitative separation. Another phenomenon represented in Fig. 1 is elucidated now that the horizontal supply of heat has been taken into account, namely, the curve of the annual mean temperature of the surface water, t_{Wm}. This falls from the Bay of Biscay to the area abreast of Ouessant, which is in good agreement with the conditions normally ruling in the neighbourhood of the Continent. Next follows an unimportant rise in temperature with, finally, farther to the east, another decrease, though less marked than at the beginning. The course of the air temperature t_{Am} reflects the water-temperature curve but shows a less modulated fall with progress to the eastern Channel. This behaviour of the annual mean values may be regarded as the effect of the heat supply, which, as was explained before, is the result of the conjoint effects of the tidal mixing process and the water balance. Damping of the annual variation, delay in the setting-in of the annual extreme values, and increase in the annual means of the air temperatures, are the phenomena which entirely determine the favourable climatic conditions in the Channel. These could not possibly occur in this form did not the mixing caused by the tidal streams exercise its influence.

In addition, the high annual variation of the heat content in the Channel exercises influences of an especially oceanographic character, as a result of which the specific volume of the whole water column

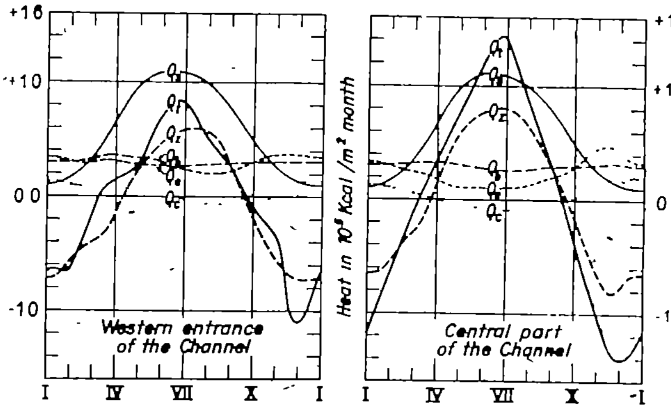

Fig. 3. Mean heat budget of the water of the English Channel in two examples. Q_s, heat absorbed from incoming radiation from sun and sky; Q_b, heat lost by back radiation from the sea surface; Q_h, heat lost by convection of sensible heat to the atmosphere; Q_e, heat lost by evaporation; Q_v, heat balance in vertical direction: $Q_v = Q_s - Q_b - Q_h - Q_e$; Q_t, heat used for explaining the observed annual temperature variation of the water from surface to bottom

PHYSICS Dept. Science

inside the Channel has a higher annual variation than that of the area outside. It follows that the geopotential topography of the sea surface is subject to greater changes in the course of a year. D_S in Fig. 1 indicates its situation in summer, and D_W in winter. Both are referred to the 100-decibar surface. D_S–D_W, which amounts to 6 dyn. cm. outside the western end of the Channel, reaches 13 dyn. cm. in the central part of the Channel. From this it follows that there is a change in the gradient of the geopotential topography, especially in the section Ouessant/Guernsey, as can be seen in Fig. 1. The increase of D_S and the concurrence of the Coriolis forces provoke a cyclonic component of motion superimposed on the general drift current and driving the inflow towards Brittany, and the outflow towards Cornwall. In winter, the situation is reversed; then, the decrease of D_W contributes to the formation of an anticyclonic component of motion, which drives the inflow towards Cornwall and the outflow towards Brittany. Observation confirms this annual change in the circulation system of the water masses. According to the monthly charts of surface salinity by J. R. Lumby[9], the tongue of water of high salinity and reaching from the Bay of Biscay to the western Channel advances as far as Brittany in summer and as far as Cornwall in winter. The low-salinity water of the Bay of St. Malo, urged by the anticyclonic component of motion, advances in winter to the west beyond Ouessant; in summer, on the other hand, the cyclonic component of motion drives it back into the inner part of the Bay of St. Malo.

A series of causal relations could be quoted which, in the end, could all be traced back to the effect of the tidal mixing process. This may be expected to prevail similarly in other areas having pronounced tidal streams, such as the Irish Sea, the Minch Channel, the waters north of Scotland, and the southern North Sea, where the effect of the tidal mixing process on the layering of the water has been proved[10]. Thanks to the large and varied mass of observations available, the English Channel appeared to be particularly well suited for demonstrating the influences which tidal streams exert on oceanographic and climatic conditions.

STRUCTURE OF CLATHRATE COMPOUNDS*

By H. M. POWELL

Chemical Crystallography Laboratory, University of Oxford

THAT certain of the chemical elements will unite together to form new substances, their chemical compounds, is well known and to some extent explained. It is also known that a compound capable of a separate existence of its own may combine with an element and that two such compounds may unite by simple addition: $L + M \rightarrow LM$.

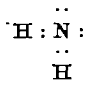
Some time ago, the conviction formed that the ordinary manifestations of these interactions between old substances to form new are the outward signs of inner rearrangements of atoms that make up the invisibly small units of both old and new. Since it became apparent that atoms are not the indivisible units that their name states them to be, the explanation for the bonding of one with another has been sought in the interaction of their component parts. The essentially electrical structure of the atom with some of the pieces positively or negatively charged has been demonstrated, and, since similar charges repel each other and dissimilar charges are mutually attracting, the supposition arose that these interactions could cause atoms to hold together.

Although the law of force between charges is simple, its application to the whole complex system of electrical charges in uniting atoms is difficult, and the problem is for the most part treated by approximate methods. The linkage of atoms is related to the disturbances of a few of their negatively charged electrons, which are sometimes spoken of as being farther than others from the centre of the atom. These electrons are less firmly bound to the positive nucleus than some of the inner ones which partly screen them from the nuclear charge, and in a complex atom they form only a small part of the whole. Their rearrangements by transference from one atom to another or sharing between them provide the binding forces.

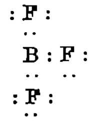
Certain groupings of electrons, notably a completed outer group of eight, are particularly stable. This is illustrated by the known sequence of atoms according to the number of electrons surrounding the nucleus. Atoms, which in the uncombined state already have the stable configurations, have no chemistry; they are the so-called inert gases, helium, neon, argon, krypton, xenon and emanation, and they are commonly stated to form no compounds; their electrons do not need any rearrangement. Much of the simpler chemistry of the neighbouring atoms in the atomic number sequence is interpreted as the rearranging of their electrons to form similar stable groups around atoms which in their uncombined state do not have them.

When transference of an electron takes place, the atoms become positively or negatively charged, according to their loss or gain of electrons, and the resulting ions are mutually attracted, as are other oppositely charged bodies. Atoms may complete the desired stable groups by sharing what they have when one or both are deficient in electrons.

When a particular atom has a stated set of electrons, and some of the outer ones are shared to form two or more bonds, the directions in space of the bonds relative to each other are fixed. They adopt one or other of a number of known patterns, and from this they vary little, whatever may be the nature of the groups that they bind to the atoms concerned. Electron sharing usually results in the build-up of some familiar stable group; but even when the more urgent electronic requirements of combining atoms have been satisfied, and a stable compound formed, there remain further possibilities of combination. For example, of the molecules of ammonia (NH_3) and boron trifluoride (BF_3),



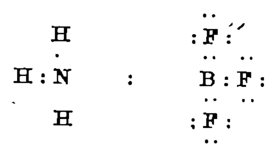
$$\begin{array}{ccc} & \mathrm{H} & \\ & \cdot\cdot & \\ \mathrm{H}: & \mathrm{N} & : \\ & \cdot\cdot & \\ & \mathrm{H} & \end{array}$$



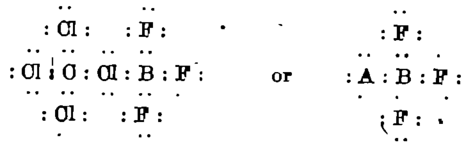
$$\begin{array}{ccc} & \dot{} & \\ : & \mathrm{F} & : \\ & \cdot\cdot & \\ & \mathrm{B} & : \mathrm{F} : \\ & \cdot\cdot & \cdot\cdot \\ : & \mathrm{F} & : \\ & \cdot\cdot & \end{array}$$

* Substance of a Friday Evening Discourse entitled "Atoms Encaged—A New Type of Compound" delivered on April 28.

the former has for all atoms an inert gas electronic arrangement which is helium-like for hydrogen, neon-like for nitrogen; in the latter, the group of six electrons around the boron atom is stable, but it can be increased to eight by addition of NH_3 to give:



If the paper drawings of electronic dots alone were needed, this process could be extended: for example,



But these atomic linkages do not take place. Such compounds of argon and boron trifluoride were reported, but their existence has been disproved. This form of sharing does not happen because too much energy is required to make argon or even xenon give up a share of its electrons.

A further type of linking, which causes the union of molecules, is known as the hydrogen bond. For the present purpose it is sufficient to say that it forms only between a few groups, commonly between hydroxyl (OH) groups, and although not so precisely limited in space arrangements, the directions of hydrogen bonds are restricted in a manner analogous to that of the electron-pair bonds.

For some substances formed by the addition process $L + M \rightarrow L.M$, it is inevitable that for a time there should be a meaningless full stop inserted between L and M; it must be emphasized that this does not represent an electron. Although many addition compounds are eventually fitted into the known scheme of interatomic bonding, there exist many crystalline molecular compounds for which no formulation is apparent, and the suspicion arises that between the molecules there is no chemical binding of any of the kinds already described.

These associations of molecules are attributable to parts of the total interatomic forces so far neglected. Between all molecules, additional, usually much weaker, forces come into play. They arise because the centres of positive and negative charges do not at all times coincide. Some molecules have permanent, some transient, dipoles or multipoles. There is a more restricted use of the term, but for convenience, all these residual attractions may be grouped together and called van der Waals forces. As a result of their operation, a multitude of substances draw their electrically neutral molecules together into crystalline forms. These forces are strong enough to hold atoms of the non-combining inert gases in crystal structures that exist at suitable low temperatures.

In a mixture of molecules, it happens, fortunately, that all those of one kind will often gather together. From an assortment of different molecules, stable regular patterns are built by the segregation of identical shapes. Sometimes, however, two substances do not crystallize separately in this way, but together make a crystalline molecular compound. In these structures, which often bear little resemblance to those of the components when they crystallize in the pure state, there are no links between the two kinds of molecules. This is shown by the observed interatomic distances, which are much greater than those commonly found between linked atoms. As an example, there is a molecular compound of *p*-iodoaniline with *s*-trinitrobenzene, one molecule of each. The two kinds of molecules pack together according to a regular repeating space pattern similar to those formed by single pure substances.

In other molecular compounds there is the same co-operation of the two components, but in some series the structural arrangements of one component dominate the whole. Thus if a paraffin is added to a saturated solution of urea in methanol, a crystalline compound is formed immediately. It consists of urea molecules arranged so as to form a structure resembling a honeycomb. In the long channels of the honeycomb the paraffin molecules are located, and if molecules of different lengths are used, different ratios of urea to paraffin are found. In general, they are not whole-number ratios and the formula is $n\text{Urea}.H$, where n is proportional to the length of the hydrocarbon molecule H.

In these uniting pairs, one partner at least is a solid when pure at ordinary temperature, at which the molecular compounds are prepared. The other is a solid or liquid. Sometimes, especially if one participant is a very volatile liquid, the molecular compound decomposes when allowed to stand in the open. A substance with van der Waals forces between its molecules so weak that it is normally a gas is therefore not likely to form similar compounds.

But a hundred and two years ago Wöhler prepared an addition compound of quinol and sulphur dioxide. He gave the composition as $3C_6H_4(OH)_2.SO_2$, and reported that it did not lose the normally gaseous sulphur dioxide on standing, but that on solution the sulphur dioxide was lost and quinol recovered. During the next sixty years, similar compounds were obtained with quinol, and a second substance such as hydrogen sulphide, hydrogen chloride, hydrogen bromide, hydrogen cyanide or formic acid. In some, the ratio of the second substance to quinol is less than 1 : 3. This is also the case with some recently added members of the series (acetylene and carbon dioxide); but others (for example, methanol and methyl cyanide) reach the 1 : 3 ratio, which is never exceeded.

There being none of the bonds mentioned earlier and, for the most volatile of these second components, no great van der Waals attractions between the components, how can these crystalline compounds exist? Why at ordinary temperatures have they no significant dissociation? What accounts for the unusual 1 : 3 ratio and its variations, and on what basis does quinol choose certain companion molecules and reject others? How, in the series that starts with water (HOH) and passes through methanol (CH_3OH), ethanol (C_2H_5OH) to the higher alcohols, is methanol alone singled out for such combination?

Application of the very penetrating method of X-ray crystal structure analysis has provided the answers. By this method the positions of all atoms in the crystal array are accurately found. Quinol molecules of the shape and size expected are revealed in the structure sufficiently separated from the other component to show that there is no chemical bonding to it. A set of these molecules link together through hydrogen bonds between their hydroxyl groups. Six oxygen atoms of six different quinol molecules form a plane hexagon. Alternate quinol molecules incline upwards or downwards from this and are linked in a similar manner through their other hydroxyl group to form a structure of the giant molecule type. This structure may be likened to the steel frame of a large building. Each girder represents a quinol molecule, and the points where six such girders meet should be replaced by a hexagon to correspond with the hydrogen-bonded hexagons. Two identical frames of this kind form and interpenetrate. They are in no way linked by chemical bonds, but are inseparable without the breaking of chemical links. This arrangement may be seen as two identical steel frames, not joined, but arranged such that the junctions of girders in one are at the centres of the rooms in the other.

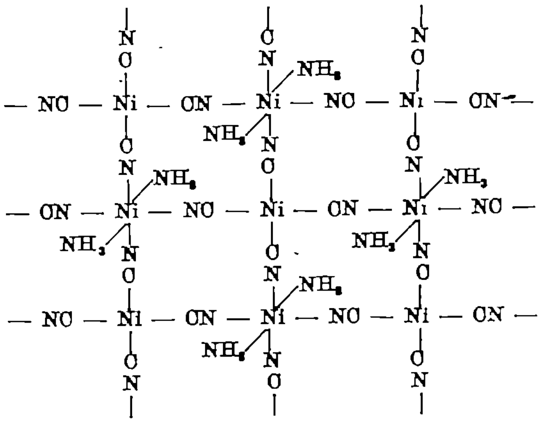
The double quinol structure is still not a very close-packed one, and between the two giant molecules there is a set of cavities, each a roughly spherical empty space of about 4 A. diameter. In these spaces reside the molecules of sulphur dioxide or other substances which form these molecular compounds. The molecule once trapped in this space cannot escape. As it approaches the walls of its cage, large forces of repulsion between it and the walls are set up. There are no holes in the surrounding structure large enough for it to escape without coming much closer than the normal van der Waals contact distance to the atoms of the quinol molecules. The structure is different from that formed by quinol itself in the absence of any molecules suitable for enclosure. Every gas molecule has one of the set of identical molecular envelopes around it. Although there will always be van der Waals forces of attraction between the cage and its occupant, these forces, which in any case are insufficient to do it, are not necessary to ensure the permanent association of the two substances. The sulphur dioxide can be released by heating, but only as a result of the breaking of the hydrogen bonds, and sublimation of quinol. Similarly, it is released when the material is dissolved in any solvent for quinol.

The chemistry of such compounds now becomes clear. There are three molecules of quinol in the material of the cage structure for every cavity formed. This explains the formula *M*.3 (quinol). It is a limiting composition, since some cages may be left empty. The selection of molecules that take part in the compound formation now loses its miscellaneous character. The enclosed molecule must be small enough to go into the space available and large enough not to escape through the available holes, the largest of which is the hexagon of oxygen atoms bound by hydrogen bonds. For this reason methyl cyanide (CH_3CN), methanol (CH_3OH), acetylene (C_2H_2) and carbon dioxide (CO_2) seemed possible participants, and proved to be so. Ethanol (C_2H_5OH) is too large; water (H_2O) is too small. The compounds with argon, krypton and xenon have been prepared by crystallizing quinol solutions in the presence of the inert gases, which are used at suitable pressures to increase the solubility. The pressures need not be very high, and if other conditions are properly controlled the argon compound can be made at 10 atmospheres or less. The products consist of crystals often a centimetre across and easily distinguishable from ordinary quinol.

Although it seems likely that many such enclosure compounds may exist, it is difficult to predict which pairs of substances will form them; but if a compound which is already known belongs to this class, there are characteristics by which it may be provisionally detected.

The series of compounds formed from ammoniacal nickel cyanide solution and a small group of organic substances provides an example. The composition is $Ni(CN)_2.NH_3.M$, where *M* is benzene, thiophene, furan, pyrrole, aniline or phenol. There is no obvious manner in which benzene may be linked to the nickel cyanide complex. The metal —C≡N— metal sequence of atoms, which may well be suspected in the cyanide complex, is a suitable cage-forming component. Homologues of benzene and of the other molecules do not form such compounds. The thiophene compound has only about a third of the thiophene indicated by the formula.

Examination by X-ray methods of the crystalline benzene compound shows that the main component of the structure is an extended two-dimensional array of groups which form a flat network:



To every other nickel atom there are attached two ammonia groups projecting above and below the network. One set of nickel atoms is surrounded by four carbon atoms in a square pattern, and the other by four nitrogen atoms of CN groups, and two ammonia groups, the six nitrogen atoms forming an octahedron.

This complex has a rigid flat structure with projecting ammonia groups which prevent the close approach of two layers. Although staggering of the projecting ammonias would make possible a closer packing, no arrangement can avoid a considerable amount of empty space. By the inclusion of a benzene molecule in each of a set of cavities left between layers, there results a structure which, as a whole, is well packed. All the molecules which are capable of combining in this way have shapes and sizes very similar to those of benzene.

The behaviour of these compounds may be applied in the chemical processes of separation, identification and quantitative analyses. They provide new and striking ways of preparing pure materials. The ordinary methods of fractionation lead to products which are likely to contain impurities of very similar physical properties to the desired substance. Further separation, for example, of two isomeric hydrocarbons of almost identical boiling point, can be extremely difficult. It is precisely at this stage of difficulty that a method of separation based on some entirely different factor is required. Two substances of such close similarity of physical properties may yet differ strikingly in the geometrical form of their molecules. Thus a paraffin may be of the straight-chain or branched-chain type. These may be separated by use of the urea compounds, because the straight chains fit into the honeycomb whereas the branched isomers cannot; but the separation of chains of different length is not a structural necessity. In clathrates, as these compounds are termed, the cage is of restricted size and, if suitable structures can be found, molecules of different lengths should be separable.

Benzene which is already of reasonable purity may be further rid of impurities, probably *cyclo*hexane, by formation of its nickel cyanide ammonia complex, which is later decomposed. A single crystallization of this kind gave a large yield of benzene, which contained 99·992 ± 0·004 molecules per cent. The ideal in this type of chemical work should be to 'tailor a suit' for any desired molecule, which could then be obtained as a molecular compound; this compound could then be removed as unwanted or used as a source of the required material.

The purification process is further illustrated by some experiments in the separation of the inert gases. No ordinary chemical componds of these elements are available for a separation, and the usual method takes advantage of their different boiling points in a fractional distillation process. Argon may be separated from neon by adjusting the pressure conditions such that the argon forms the compound with quinol but neon does not. The gases krypton and xenon, which both form compounds with quinol, may be separated in a different manner. Since the solubility is higher for xenon, there is a greater chance for xenon to become enclosed. A mixture containing krypton and xenon in the proportions of 3 : 1 was used in the standard method of preparation; the gas liberated from the crystals contained about one part by volume of krypton to three parts of xenon.

ENGINEERING EDUCATION AND TRAINING

THERE has been much controversy in recent years on the education of the engineer. An unusual feature of the discussions is that engineers have taken relatively little part. That this is not due to lack of interest in the subject is shown by the fact that during the Joint Engineering Conference held during June 4–15 in London, a whole day was devoted to papers dealing with the education and training of the engineer.

During the morning of June 13, at the Institution of Civil Engineers, Prof. J. F. Baker read a paper on "The Development and Trend of University Education in Engineering", and this was followed by "The Contribution of the British Technical Colleges to Engineering Education", by Dr. H. L. Haslegrave. As was to be expected at a Conference having as one of its objectives the recording of the contributions made during the past century by engineers to the advancement of civilization, both authors devoted considerable attention to the history of technical education in Great Britain.

While the origins of the technical colleges in Great Britain go farther back than a hundred years, to a welfare movement for working men and neglected youths and to the founding of the Society of Arts in 1754, the universities, in all but one of which there are now flourishing engineering schools, came into the field much later. It was not until a third of the nineteenth century had passed that courses of lectures, described as "Civil Engineering", were given in the University of Durham and in University College and King's College, London, and not until 1840 was any real attempt made to establish a balanced course of fundamental science and practical application.

In 1851 there existed only five university schools of engineering in Britain, chairs having been established at Glasgow, Dublin and Belfast, while the courses at Durham had been wound up. In the next twenty-five years four more were added, Owens College, Manchester, and Armstrong College, Newcastle upon Tyne, being founded, while the Universities of Edinburgh and Cambridge established chairs of engineering. It was shortly after this, between 1878 and 1890, that the most striking blossoming of advanced educational facilities occurred; no less than nine chairs of engineering being established in this period. In almost all cases the colleges owed these foundations to the generosity and ideals of local men; but they all had financial difficulties. More serious was the dual part all but Cambridge were called upon to play; the Government Department of Science and Arts instituted in 1858 having provided by means of grants a great stimulus for skilled craftsmen to attend evening classes, all other schools were centres of evening as well as day work. While the evening class students undoubtedly brought in that enthusiasm which is still so marked in the technical colleges, the dual responsibilities inevitably had repercussions on research and scholarship in the universities. Only gradually were the two activities separated and, in fact, in several cases this separation has still to be effected.

During 1900–14 the story of engineering in the universities is one of continuous and steady development, although hampered by lack of funds in spite of State aid. As in other fields, the First World War had appreciable repercussions. Apart from the sharp rise in numbers, the main effect seems to have been indirectly through changes in industry, which at last realized the advantages to be gained from the application of science to production and design problems. More universities stiffened their courses to three years post-intermediate and delayed specialization until the final year; but only Oxford and Cambridge persisted in giving an all-embracing course to a high level in the firm belief that their products possess a versatility and balance of mind which enable them to strike out with equal facility along any line they may be called upon to pursue.

The most striking change brought about by the Second World War was the doubling of the number of students, an expansion which must at least be maintained if the universities are to shoulder the responsibility of supplying the 'engineer-scientists' and development engineers needed by industry. There is evidence that the universities are alive to their responsibilities and are responding to them with a flexibility which a study of the last thirty years would scarcely lead one to expect. A number of universities are questioning the value of the formal experiments in the laboratory courses and are introducing small investigations and projects in the final year as a means of encouraging initiative and a methodical approach to new problems. Alarm at the inability of students to think and write logically has led in some colleges to formal instruction in the presentation of technical information, and in others to the use of discussion-groups; and there are other healthy signs of encouragement to undergraduates to achieve a better general education.

While all this development was taking place in Great Britain in the universities, where students get their education in the relatively easy way, the determination of the workers in industry to improve their knowledge of their work brought about an even more striking increase in the number of technical colleges. These were created from the earlier mechanics institutes from 1870 onwards, first by means of voluntary effort and later with government financial help. Evening classes were not the only activity; by 1914 there was a considerable volume of part-time day release of engineering apprentices throughout Great Britain, and this was increased after the First World War when the National Certificate scheme was born. One of the values of this scheme is its flexibility, and the syllabuses, subjects and standards have since been kept constantly under review by the Ministry of Education, the professional engineering institutions and the staffs of the colleges. Teaching of a high order has been assured for part-time students, resulting in the securing of recognized qualifications and through them of membership of the professional institutions. When the output of engineering graduates in Britain is compared unfavourably with those of other countries, the products of our senior technical colleges, which have no parallel abroad, are too often forgotten.

Since 1931 many new colleges have been erected; but this expansion has always lagged well behind the needs of industry. Since the War, two of the Percy Committee recommendations have been adopted, namely, the formation of national colleges, four of which are now in existence, and the setting up of regional advisory councils for further education. These councils have had little time to make any impression other than the production of the controversial scheme for the creation of a Royal College of Technologists. What is likely to have a greater effect upon the progress of technical colleges is the revision of salary scales which came into effect on April 1 last. Up to now the staffs of the colleges have worked with a surprising devotion and resourcefulness for woefully inadequate salaries.

In introducing his paper, Prof. Baker directed attention to a most important recent development in university education, namely, the establishment of postgraduate courses of instruction which generous help from the University Grants Committee has made possible at Birmingham, Cambridge, Edinburgh, Glasgow, the Imperial College of Science and Technology, Leeds and Sheffield. These courses have been designed for engineers whose experience in industry has concentrated their attention on relatively narrow fields. The student will choose that university which has organized a course in the particular field of his interest, and there he will return, not to do research but to attend advanced lectures, to read under supervision and to engage in laboratory work under conditions not generally available in industry and, above all, to learn how to apply science. This scheme should have far-reaching effects, integrating as it does teaching and research activities. Primarily in the interests of the undergraduate courses, the teachers engage in research or consulting work. When that makes them leaders in their particular field, they obtain extra facilities to enable them to organize postgraduate courses of instruction. The students attending these will be mature men coming straight from industry. They will contribute quite as much as they receive, so that the departments' research and undergraduate teaching will both benefit; neither will become too academic and a healthy balanced state will develop.

In the discussion that followed, in which engineers from Holland, Belgium, Australia and New Zealand joined, this scheme was applauded. Its economy over the possible alternative of extending the undergraduate course for a fourth year was stressed, and it was welcomed for its encouragement to make the undergraduate course more general. The opinion of the Conference, expressed particularly by Colonel B. H. Leeson, who opened the discussion, and Dr. Livingstone Smith, was solidly in favour of the universities making their undergraduate courses general and fundamental on the present Cambridge pattern. Prof. R. L. Lickley, while in favour of the postgraduate courses, gave the serious warning that, judging from the experience of the National College of Aeronautics, industry would not avail itself of the new opportunities. Others taking part in the discussion urged the need for a study of teaching methods, for more attention to the education of those destined to become managers, for more places in university engineering departments for the good all-round man who is in danger of extinction, and finally a strong plea was made for the granting of greater academic freedom for technical colleges.

The teaching of engineering presents peculiar difficulties compared with other subjects, because it is essentially an applied science, and practice can never be ignored. This side of the problem was dealt with in two more papers, "Practical Training of Civil Engineers" by Mr. H. J. B. Harding, and "Practical Training of Mechanical and Electrical Engineers" by Sir Arthur Fleming. Both authors gave interesting accounts of the evolution of practical training and of the schemes which are now available. Because engineering employment is diverse, no one single scheme can cover adequately the general needs of the whole profession, nor can a single scheme cover the individual needs because the entrance levels to the profession are different. It was interesting that both authors advocated an increase in the facilities for 'sandwich' courses based on works training. Certain institutions, notably the University of Glasgow, so arrange their courses that the students can spend five months at a stretch in or on works. Mr. Harding has had such men working for him. At the end of the five-months period, they leave an unexpected vacuum behind them in the organization. Mr. Harding suggested that selected colleges should establish double-sandwich courses of, say, five and a half months each. The employer could then engage students in pairs, and as each half-year's course ends they could change places so that one is always available. He then somewhat ingenuously stated that, as the total number of students would not increase, no great increase in teaching staff would be required. No university teacher could go on indefinitely teaching for eleven months in the year; but there is something in the scheme where an institution wishes to double the number of students turned out. It would mean doubling the teaching staff—no easy task to-day—but would entail no addition to its buildings, equipment or appreciably to its laboratory staff.

Though Capt. A. M. Holbein, in opening the discussion, was able to say that he detected an awakening of interest among industrial companies as well as among individuals, and a sense of responsibility for giving an all-round training as was done by the ancient trade guilds, this was not supported by the other contributors to a somewhat disappointing discussion.

The impression left by the papers and their reception was that Great Britain can deal successfully with the education and training of the technician and the general run of professional engineer, the classes who form the backbone of industry. There is a strong partnership between the technical colleges and the engineering industry, and, though there is plenty of room for better equipment and more generous treatment of teachers in the colleges, they are doing good work and will continue to do this and even better so long as they have the determination to develop their own methods and do not ape the universities. The problem industry has not solved is how best to treat the product of the university. No one denies the urgent need for a steady supply of these highly educated men, and everyone at the Conference agreed that the universities in their undergraduate courses should concentrate on the fundamentals of general engineering science; but this is less than half-way to making the men engineers able to use all their talents. Something more is needed than a two-year graduate apprenticeship followed by the usual haphazard and extravagant method of obtaining experience. The only certain way a young man now has of being given a real chance to develop fully is to be born the son of an engineering magnate. This is a restricted class, and unless leaders of industry and the professions are prepared to 'adopt' more young men from the universities rather than just to use them, then fewer and fewer of the best products will turn devotedly to engineering, ignoring the easier paths open to other scientific workers and the attractions of other professions where the training is better organized and the rewards and social standing are higher.

OBITUARIES

Mr. László J. Havas

László Jenő Havas died on June 9 at Colmar, in Alsace, after an operation. He was born in 1885, of Hungarian nationality, and studied at Budapest and at several other universities; he also worked at Rothamsted Experimental Station. He was a man of wide culture, and an excellent linguist. The problem which primarily interested him was the relationship between plant and animal cancer; and many of his publications testify to his interest in tumours and other plant abnormalities induced by *Bacterium tumefaciens* and chemical agents. It is not widely realized that Havas was the first to apply colchicine in such investigations (*Nature*, 139, 371; 1937); and it was while he was in Brussels in A. P. Dustin's laboratory that he discovered the effect of colchicine on cell-division that has had wide repercussions in genetical work. This was announced at the Congress of Anatomists held at Marseilles in March 1937. (An account of early researches with colchicine has been given by J. M. Krythe and S. J. Wellensiek, *Bibliographia Genetica*, 14, No. 1, 1; 1942).

Havas regarded as his principal paper that on the gradual evolution of polyploidy and other changes in *Pelargonium zonale* (*Bull. Acad. Roy. Belgique*, (5), 28, 318; 1942); but with this also he was unfortunate. Published during the German occupation of Belgium, it attracted little notice except from the Nazis, who destroyed all reprints. Havas suffered under two despotisms, and lost all his belongings in Brussels and Budapest, including his library. After the War he found asylum in France and existed precariously on grants; but his Belgian-born widow is left unprovided for. There were no children.

Hugh Nicol

Dr. I. E. Balaban

Isidore Elkanah Balaban, head of the Pharmaceutical Research Department of the Geigy Company, Ltd., Manchester, was killed on May 23 when he fell between a train and the platform on alighting at London Road Station, Manchester.

Dr. Balaban showed an early aptitude for scientific work. During the First World War, he served with the Manchester Regiment and later the Special Brigade, Royal Engineers. He then returned to the College of Technology, Manchester, and after graduation, became research assistant to Dr. F. L. Pyman. He worked on glyoxalines and took his M.Sc. and Ph.D. degrees. On Pyman's recommendation he secured a temporary post at the National Institute for Medical Research, Hampstead, where he collaborated with Dr. Harold King in problems of chemotherapy involving the preparation of analogues of Bayer 205 and a study of their substantive properties, glyoxalines containing arsenic and gold compounds.

Balaban then entered on an industrial career, joining first of all the staff of May and Baker, Ltd., under Dr. A. J. Ewins, and ten years later he left to take up a post in the research department of Imperial Chemical Industries, Ltd., at Blackley, thus fulfilling a desire to return to his native city. While in Manchester he was awarded the degree of D.Sc., and he joined the Geigy Company, Ltd., in 1941 to develop the pharmaceutical side of the firm's activities. During these years in commercial firms, Balaban published a number of scientific papers, all having a bearing on chemicals of potential use in pharmacy or medicine.

Balaban was a keen worker in the field of medicinal chemistry and avidly kept in touch with all the latest developments. Of unassuming nature, he surprised his most intimate friends by his love of ornithology and horticulture; thus he thought nothing of paying a visit to St. Kilda to see the sea-birds in their natural surroundings. He will long be remembered by his friends and colleagues for his enthusiasm and honesty of purpose, and many will mourn his untimely end.

We regret to announce the following deaths:

Prof. R. St. A. Heathcote, formerly professor of pharmacology in the Welsh National School of Medicine, on May 19, aged sixty-two.

Prof. F. Marguet, *correspondant* for the Section of Geography and Navigation of the Paris Academy of Sciences, and formerly professor of astronomy in the Naval School of Brest, at Villeneuve-Loubet, on June 2, aged seventy-six.

Mr. G. Udny Yule, C.B.E., F.R.S., formerly University lecturer and reader in statistics, University of Cambridge, on June 26, aged eighty.

NEWS and VIEWS

Radio-Astronomy at Manchester:
Prof. A. C. B. Lovell, O.B.E.

Dr. Alfred Charles Bernard Lovell has been appointed to a newly created chair of radio-astronomy in the University of Manchester. Dr. Lovell was born in 1913 and entered the University of Bristol in 1931. In 1936 he was appointed assistant lecturer in the Physics Department at Manchester; he was made lecturer in 1945 and reader in 1948. During the war years, Lovell was occupied with radar research in the Telecommunications Research Establishment, and accompanied this famous institution in its war-time wanderings from Bawdsay via Dundee and Swanage to Malvern. He was particularly concerned with the development and installation of airborne radar in the air force, and his services were recognized by the award of an O.B.E.

Soon after returning to Manchester in 1945, Lovell set up a radar set, on loan from Anti-Aircraft Command, in the courtyard of the University and began an investigation of radar echoes from meteor trails. Soon driven out of the city area by electrical interference, the radar set was transferred to a field at Jodrell Bank in Cheshire, near the University Botanical Station. Five years later, aided by generous financial support from the University and the Department of Scientific and Industrial Research, there has come into being a large and well-equipped research station, with some eighteen research workers engaged in many branches of the new subject of radio-astronomy. The Jodrell Bank Research Station is now, and will remain, an integral part of the Physical Laboratories of the University, of which the director is Prof. P. M. S. Blackett. Together with the pioneer work of J. S. Hey, of the Ministry of Supply Operational Research Station, and of Martin Ryle at Cambridge, radio-astronomy is now in a very flourishing state in Britain. Among the important contributions from Jodrell Bank has been a detailed survey of meteor activity, which led to the discovery of very intense summer showers occurring in daylight and so unobservable by visual means. This work has greatly changed our present picture of meteor activity. The first radar echoes from the aurora borealis stream were made at Jodrell Bank in 1949. Quite recently, radio noise from the Andromeda Nebula has been detected and shown to be of the same order of magnitude compared with visual light as for our galaxy.

Textile Chemistry at Manchester:
Mr. F. Scholefield

Mr. F. Scholefield is retiring from his position as head of the Department of Textile Chemistry in the Manchester College of Technology on reaching the age limit. He was first appointed, as lecturer in textile chemistry, in 1926. Prior to that he had been one of Prof. A. G. Green's first students in the Department of Colour Chemistry and Dyeing at what was then the Yorkshire College, Leeds. After a short period in Read Holliday and Sons, Ltd.'s dyehouse at Turnbridge, he became chemist to Francis Hinde and Sons, Ltd., at Norwich, and then, successively, chief chemist to Henry Ashwell and Co., Ltd., Nottingham, R. P. Lawson and Sons, of Manchester, and in 1912 to Burgess Ledward and Co., and later manager of their dyehouse. At the Manchester College of Technology he initiated the comprehensive work on the action of light on cotton dyed with vat dyes, for which he was awarded the Research Medal for 1928–29 of the Worshipful Company of Dyers. This work has become classical, and his research work was further recognized in 1947 by the award of the Gold Medal of the Society of Dyers and Colourists, of which he is now president, in recognition of his "Exceptional Services to the Society in the advancement of Tinctorial Technology both in theory and practice". Still more recently he has been awarded at the Brighton Conference of the Textile Institute last May the Institute's Medal for distinguished services to the textile industry. Under Mr. Scholefield the Department of Textile Chemistry in the College of Technology has risen to the front rank in both teaching and research, and he leaves it with a reputation in industrial circles that fully justifies its position in the Faculty of Technology of the University of Manchester.

Gold Coast College of Arts, Science and Technology:
Appointments

The Secretary of State for the Colonies (Mr. James Griffiths) has announced the following appointments in the new Gold Coast College of Arts, Science and Technology: Prof. J. P. Andrews, vice-president and professor of physics in University College, Ibadan, Nigeria, to be principal-designate; Mr. R. Pattison, head of the Department of Engineering and Building, South-East Essex Technical College, to be head of the Engineering Department. The Gold Coast College of Arts, Science and Technology is being established at Kumasi, and work is in progress on the permanent buildings. The College is to be an autonomous institution, complementary to the Gold Coast University College, and will provide courses of higher technical education (including engineering) and teacher-training. Two hundred students of the Achimota Teacher Training College and a hundred other students are expected to move to Kumasi to start the new College this month. A sum of £350,000 has been allocated under the Colonial Development and Welfare Acts for capital expenditure on the College—which is likely to be in the region of £2,000,000.

Prof. Andrews, who is forty-nine, was educated at Leyton County High School and Queen Mary College, University of London, where he obtained his B.Sc. in 1921 and D.Sc. in 1931. He has been professor of physics at Ceylon University College and has carried out research on problems of the ionosphere. During 1939–44 Prof. Andrews was head of the Physics Department in Bradford Technical College, and among other duties was responsible for organizing a scheme for training Service personnel in radio. He then became assistant professor of physics in Queen Mary College, University of London, and in 1949 was appointed to University College, Ibadan. Mr. Pattison has been head of the Department of Engineering and Building at the South-East Essex Technical College since 1943. After holding lectureships in mechanical engineering at Birmingham and Leicester Technical Colleges, he was appointed head of the Engineering Department at Burnley Municipal College in 1938, and superintendent of classes to the Board of Industrial Training, Trinidad, in 1940.

Spotlight on Science

Thirty or more years ago the means of promoting the layman's interest in science took the form of articles containing details of simple experiments which the layman could carry out at home. To-day, increasing awareness of the social impact of science has changed the nature of popular science journals and now they usually seek to explain not only the mechanics of important scientific discoveries but also their significance for man and society. This is well brought out in a new journal called *Spotlight on Science*, which has been written by Dr. J. Gordon Cook for "the man in the street and his family". The first issue of this journal consists of notes and articles on such topics as bee behaviour, prospecting in Antarctica, high-frequency radio, fluorine, computing machines, mono-sodium glutamate, meteorology, the extraction of elements from sea-water, and the effects of environmental conditions on human beings. Each article is well written and shows that the author has taken considerable pains over the details of his information and the means of making it clear. Nine useful photographs add to the attractiveness of the journal; but these would have been more effective if spread throughout the whole journal rather than concentrated in the first half. Details of the journal may be obtained from the Merrow Publishing Co., Ltd., 23 Ganghill, Guildford, Surrey.

Bollettino dell'Istituto di Alimentazione e Dietologia

THE first number of the bulletin of the Institute of Nutrition and Dietetics, Rome, was issued in August 1950 and includes a description of the work that the Institute proposes to undertake (*Bollettino dell'Istituto di Alimentazione e Dietologia*, 1, No. 1, August 1950; pp. 56. 1, No. 2, October 1950; pp. 64. Rome: Editore 'Il Pensiero Scientifico). It appears that the founders of the Institute were fully alive to the ramifications of the subject of nutrition, for the work envisaged ranges from experimental food production to fundamental laboratory studies in physiology and biochemistry, and includes food technology, catering and dietetics in health and disease. The Institute is also to offer courses in nutrition at various levels, intended for medical officers, nurses, teachers, administrators, economists, agriculturalists, catering officers and cooks, and also non-technical courses for the man-in-the-street and the housewife. All these plans are in concordance with the resolutions adopted by the United Nations Food and Agriculture Conference at Hot Springs in 1943 and repeatedly re-emphasized by the Food and Agriculture Organization ever since. If these plans can be adequately carried through, Italy should be able to evolve and maintain a scientific food policy from which her people would derive great benefit. But to what extent this Institute will be able to influence government policy remains to be seen. The first two issues of the bulletin present reports of work already in progress (for example, on protein levels and albumin/globulin ratios in cases of gastric or duodenal ulcers or carcinoma of the digestive tract) and also diet sheets and recipes for therapeutic use. The second issue also includes very full extracts of the publication by the Food and Agriculture Organization on calorie requirements.

Blight-resistance in Potato

DR. WILLIAM BLACK, working at the Scottish Plant Breeding Station, Edinburgh, has produced several potato varieties resistant to attack by blight, *Phytophthora infestans*. He describes, in a recent paper (*Proc. Roy. Soc. Edinburgh*, B, 64, Part 2, No. 10; 1950), the occurrence of three strains, A B and C, of the fungus. Strains B and C are more virulent than the common strain A, from which they probably arose by mutation. Specialized strains of blight may, under test conditions, alter in virulence; but each can be maintained in continuous culture on a host plant to which it is specially adapted, without appreciable change. This mutability of pathogenic fungi is an incubus to the plant breeder; but Dr. Black now reports breeding experiments for resistance to all three strains. The existence of three genes is postulated: *Rb*, conferring resistance to strains A and B; *Rc*, resisting A and C; and *Rbc*, giving resistance to all three. Each gene is independent of the other in producing its effect, and is inherited independently in simple Mendelian fashion, though there is an excess of recessive individuals. The wild species *Solanum demissum* provides the source of resistant genes.

University Education and Subsequent Careers

AN excellent pamphlet, "Introduction to a University" (pp. 47; 1951), has been issued by the University of Birmingham and is designed to assist some of those who now have the chance of a university education but have had little opportunity of finding out what are the essentials of such an education. The greater part deals with the various careers open to university graduates in science and the humanities; but the pamphlet starts with a brief account of the main ideas about universities in general at the present time, especially as they relate to the undergraduate. This is followed by some account of the University of Birmingham itself and of undergraduate life at that University. There is a section on qualifications for admission to the University of Birmingham, and some information on salary scales in various careers is appended.

1950 Conference of British Universities

A REPORT of proceedings at the Conference of the Home Universities, held at the University of London during December 15–16, 1950, has now been published (pp. 119; London: Association of Universities of the British Commonwealth, 1951; 1*s*.). It includes the text of addresses by Profs. W. Fisher Cassie, T. S. Simey, Sir Lionel Whitby and R. D. Waller at the session on "The University as a Regional Focus", by C. E. Escritt and T. R. Henn at the session on "National Service and the Universities", and by Dr. G. V. Allen and Sir Ronald Adam at that on "Overseas Students in British Universities", as well as summaries of the discussions.

University of London: Appointments

DR. BERNHARD KATZ, reader in experimental physiology in University College, has been appointed to the University chair of biophysics tenable in University College from January 1, 1952. The following titles have been conferred in respect of posts held at the places mentioned: professor of applied mechanics in the University on Dr. Hugh Ford (Imperial College of Science and Technology); professor of technical optics in the University on Dr. W. D. Wright (Imperial College of Science and Technology); professor of veterinary physiology in the University on Dr. E. C. Amoroso (Royal Veterinary College); professor of veterinary pathology in the University on Mr. T. J. Bosworth (Royal Veterinary College).

Leverhulme Research Fellowships, 1951

THE following awards for research, tenable for periods up to two years, and for the subjects mentioned, have been made by the trustees of the Leverhulme Fellowships: *Fellowships:* T. J. Dunbabin, fellow and reader in classical archæology, All Souls College, Oxford (Greece and the Orient in the eighth and seventh centuries, B.C.); Dr. R. F. Fortune, senior lecturer in anthropology, University of Cambridge (investigation of change in central New Guinea highlands societies since pre-conquest observations in 1935); Miss P. M. Kemp, formerly lecturer, University of Allahabad (household economy and technology of some tribal communities, Punjab); M. C. K. Tweedie, Laboratory of Human Nutrition, University of Oxford (statistical estimation problems in non-Gaussian distributions). *Research Grants:* Miss B. de Cardi, assistant secretary, Council for British Archæology (an exploratory survey of prehistoric sites on the eastern borders of Baluchistan); Mrs. S. Davis, Extra-Mural Department, University of Manchester (agriculture in Cheshire, 1750–1850, in relation to contemporary industry); R. C. Ellis, education officer and headmaster, Basutoland High School, Maseru (Basotho indigenous songs and verse); J. M. Hartog, joint reader, Oxford and Cambridge Spitsbergen Expedition, 1951 (photographic and cartographic work in connexion with the Expedition); E. M. Kalinga Prize for Scientific Popularization

AN international annual prize of £1,000 sterling for the best works of scientific popularization has been established by Mr. M. B. Patnaik, an Indian industrialist, and will be awarded under the auspices of Unesco. The prize will bear the name of Kalinga, the empire which covered part of India and Indonesia three centuries before the Christian era, and which was conquered by the Emperor Asoka, who resolved, on the occasion of his conversion to Buddhism, never again to resort to the use of armed force. In co-operation with the International Council of Scientific Unions, Unesco will draw up and publish the rules for competition for the prize; and the first award will be made in 1952. Further information can be obtained from Unesco, 19 Avenue Kleber, Paris XVI^e.

Announcements

PROF. A. A. HALL, Zaharoff professor of aviation in the University of London and head of the Department of Aeronautics, Imperial College of Science and Technology, has been appointed director of the Royal Aircraft Establishment, Farnborough, in succession to the late Mr. W. G. A. Perring. Prof. Hall worked at Farnborough during 1938–45, before going to the Imperial College (see *Nature*, August 19, 1944, p. 234).

THE honorary degree of D.Sc. of the University of Birmingham has been conferred on Sir James Chadwick, master of Gonville and Caius College, Cambridge, Sir Robert Davis, inventor of the Davis submarine escape apparatus, and Sir John Simonsen, director of research, Colonial Products Research Council.

DR. G. L. S. SHACKLE, reader in economic theory in the University of Leeds, has been appointed to the Brunner chair of economic science in the University of Liverpool.

THE following appointments have recently been made in the University of Sheffield: Dr. M. A. G. Kaye to be lecturer in biochemistry; Dr. W. S. Bullough to be honorary lecturer in zoology.

DR. A. M. MACBEATH has recently been appointed lecturer in mathematics in the University College of North Staffordshire. The following have been appointed assistant lecturers in the subjects shown: E. M. Yates and Dr. Monica M. Cole (geography), Dr. D. E. Davies and A. A. Shepherd (physics), T. H. White and H. Spedding (chemistry), Ruth M. Badcock (biology), F. Moseley and R. Barrass (geology).

THE Adams Prize for 1949–50 of the University of Cambridge has been awarded jointly to the following, for essays on the subjects mentioned: Dr. G. K. Batchelor ("The Theory of Homogeneous Turbulence"); Mr. W. R. Dean ("Problems in the Motion of an Incompressible Viscous Fluid"); Dr. L. Howarth ("Some Aspects of Boundary Layer Theory").

THE British Welding Research Association announces the following appointments: Dr. Nicol Gross, to be assistant director of research, while remaining in charge of the Association's research station at Abington; Dr. K. Winterton and H. E. Dixon, to be chief metallurgists, the former for ferrous metals, and the latter for non-ferrous metals; C. L. M. Cottrell and P. T. Houldcroft, to be assistant chief metallurgists for ferrous and non-ferrous metals respectively.

SIR WILLIAM TAYLOR, a member of the Nature Conservancy and formerly director-general of the Forestry Commission, has been appointed a member of the National Parks Commission to fill the vacancy created by the resignation of Mr. E. W. Wimble.

THE first two volumes of the proceedings of the polarographic congress, held in Prague during February (see *Nature*, March 24, p. 464), are now ready. Volume 1 contains forty-four communications, in English, German, French or Italian, sent as contributions to be published in honour of Prof. J. Heyrovský's sixtieth birthday (about 550 pp.), and abbreviated papers presented at the Congress in Russian, German, English or French (about 200 pp.). Volume 2 presents a full bibliography of polarography (1922–50), revised by Prof. Heyrovský and his collaborators (about 250 pp.); Russian polarographic publications are quoted in Russian characters. Inquiries about these volumes should be sent to Orbis-Export-Import, Prague I., Národní 37, Czechoslovakia.

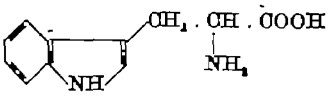
INTERMEDIARY METABOLISM OF TRYPTOPHAN

By Dr. C. E. DALGLIESH, Dr. W. E. KNOX* and Dr. A. NEUBERGER, F.R.S.
National Institute for Medical Research, Mill Hill, London, N.W.7

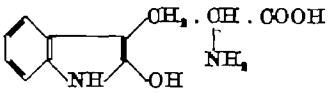
CONSIDERABLE advances have been made in recent years in our knowledge of the metabolism of tryptophan, and the experimental results suggest a general similarity of the enzymic reactions concerned in mammals, insects, fungi and bacteria. From the cumulative evidence obtained in studies with these widely different organisms, it would appear that the following represents one major pathway of tryptophan metabolism: tryptophan → formylkynurenine → kynurenine → 3-hydroxykynurenine 3-hydroxyanthranilic acid → nicotinic acid. In spite of the large volume of work in this field, much remains to be done on the elucidation of the enzyme systems involved, on the identification of postulated and as yet unknown intermediates, and on the study of alternative pathways. The work to be described was undertaken to fill some of these gaps.

First Step in the Oxidation of Tryptophan

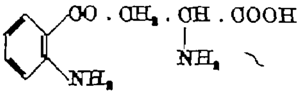
It has generally been assumed that tryptophan (I) is first oxidised to α-hydroxytryptophan (oxindolylalanine, II) and that this compound is then transformed with uptake of one further atom of oxygen to kynurenine (III). Support for this hypothesis was provided by the isolation[1] of oxindolylalanine from the hydrolysate of phalloidine, a toxic peptide present in the deathcap (*Amanita phalloides*), and also by the observation of Butenandt *et al.*[2], that (II) had some activity as precursor of the eye-pigment in mutants of *Drosophila melanogaster*. Various attempts to prepare oxindolylalanine have been made, but it was not until recently that this amino-acid has become available. Two independent syntheses[3,4] have been reported, and it has thus become possible to test this hypothesis.



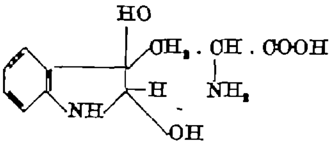
I



II



III



IV

The results obtained in this laboratory indicate clearly that oxindolylalanine is certainly not a normal intermediate in tryptophan metabolism. Thus, it has been found that the patterns obtained on paper-chromatographic examination of urines from normal or pyridoxine-deficient rats after feeding oxindolylalanine are quite different from those obtained after feeding supplementary tryptophan. After feeding tryptophan no oxindolylalanine can be detected, and after feeding oxindolylalanine none of the usual intermediates of tryptophan metabolism (see below) can be detected. Moreover, the liver tryptophan peroxidase–oxidase system of Knox and Mehler[5] was found to be quite inactive towards oxindolylalanine. Japanese workers[6] have shown that oxindolyalanine is not metabolized by *Pseudomonas* which had been adapted to tryptophan and kynurenine. Recently, Mason and Berg[7], using liver and kidney slices, have also suggested that oxindolylalanine is not a tryptophan metabolite.

There is also some doubt as to whether oxindolylalanine is, in fact, a natural product. Cornforth, Dalgliesh and Neuberger[8] have pointed out that the ultra-violet absorption of phalloidine indicates strongly that the oxindole structure is not preformed in the intact molecule, and it was suggested that the oxindolylalanine obtained on hydrolysis may be a degradation product of a 2-substituted indole. The low activity of oxindolylalanine observed by Butenandt *et al.*[2] in the eye-pigment test may still be due to an enzyme oxidizing oxindolylalanine to kynurenine in the larvæ; but it appears to us more probable that the results can be explained by the observation that oxindolylalanine, after standing in solution for some days, is largely decomposed, and among the decomposition products kynurenine may be detected.

The finding that formylkynurenine may be formed enzymically from tryptophan *in vitro* suggests that the indole ring is split oxidatively between C^2 and C^3. This may proceed by a hydroxylation mechanism giving as the first product of tryptophan oxidation 2 : 3-dihydroxy-2 : 3-dihydrotryptophan (IV)[5], which could then be further oxidized to formylkynurenine. No direct evidence for (IV) has, however, yet been encountered.

Excretion of Tryptophan Metabolites by Pyridoxine-deficient Rats

The urine of pyridoxine-deficient rats fed supplementary L-tryptophan, which has previously been shown to contain xanthurenic acid[9], is particularly rich in tryptophan metabolites. The urine obtained from pyridoxine-deficient rats fed 0·1 gm. L-tryptophan per day for one or two days was treated, after acidification and removal of insoluble material, with mercuric acetate. The precipitate was decomposed with hydrogen sulphide and the solution chromatographed on paper using (mainly) butanol-acetic acid. Under ultra-violet illumination at least nine strongly fluorescent spots appear (Fig. 1; under the conditions used tryptophan itself does not fluoresce). Strips of the chromatograms were also treated with ninhydrin, and with the reagents of Ehrlich, Hellmann[10] and Pauly. In addition, the spots were extracted into buffer (*M*/5 phosphate, *p*H 7·0, diluted 1 : 10) and the solutions examined spectroscopically. Samples of the urine were also hydrolysed with 5*N* hydrochloric acid in a sealed tube at 100° for one hour, and the hydrolysates re-examined.

Not all the spots have as yet been identified; but various conclusions can be drawn. None of the spots is given by the urines of normal rats fed similar amounts of tryptophan, or by the urines of pyrid-

---

* Special Research Fellow of the United States Public Health Service

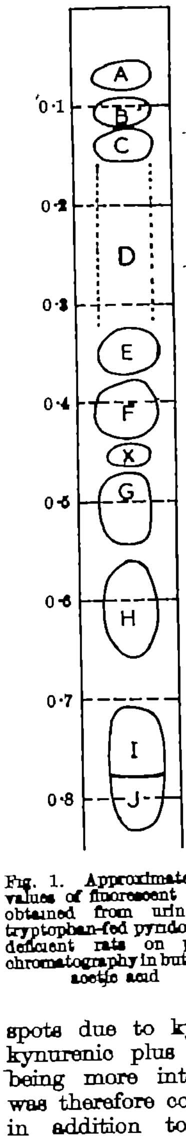


Fig. 1. Approximate R_F values of fluorescent spots obtained from urine of tryptophan-fed pyridoxine-deficient rats on paper chromatography in butanol-acetic acid

oxine-deficient rats not receiving tryptophan supplement. The conclusion is thus justified that these spots represent products of tryptophan metabolism accumulated or excreted as a result of pyridoxine deficiency.

Spot *F* is due to kynurenine, and spot *E* to 3-hydroxykynurenine. The presence of hydroxykynurenine is worthy of note. It has been found in *Calliphora*[11] and *Bombyx mori*[12]; but so far as we are aware has not previously been reported in the excretion of mammals. Its recognition in the urine of pyridoxine-deficient rats supports the concept that 3-hydroxykynurenine is an intermediate in the tryptophan metabolism of vertebrates. Spot *H* is due to a mixture of kynurenic and xanthurenic acids.

Spots *A*, *C*, *I* and *J* gave ultra-violet spectra identical in type with those of kynurenine and hydroxykynurenine. The spectrum of spot *X* resembles that of spot *H* closely, while the spectrum of *B* is somewhat similar. The assumption that *A*, *B*, *C*, *X*, *I* and *J* represent derivatives of the two kynurenines and of the two quinoline-carboxylic acids is supported by the fact that after hydrolysis only the spots due to kynurenine, hydroxykynurenine and kynurenic plus xanthurenic acids remained, these being more intense than before hydrolysis. It was therefore concluded that the urine contained, in addition to kynurenine, hydroxykynurenine, kynurenic and xanthurenic acids, comparable quantities of conjugation products of these substances. *D* is a region of weak general fluorescent and ninhydrin-positive background without outstanding spots, and *G* has as yet been little investigated but is probably also a conjugated metabolite.

The identity of spot *J* was definitely established, and the identity of spot *I* can be postulated with high probability. Spot *J* agreed in chromatographic and chemical behaviour in all respects with synthetic N^{α}-acetyl-DL-kynurenine, and the identification was strongly supported by the following experiment: A pyridoxine-deficient rat was fed at the same time 0·2 gm. L-tryptophan and 3·0 mgm. sodium acetate labelled in the methyl group with carbon-14 (36·6 μC.). A chromatogram was obtained in the usual way and the relative radioactivities of the spots were determined by a mechanical scanning technique[13]. Fig. 2 shows that the greatest radioactivity corresponds to spots *I* and *J*. It is suggested that spot *I* corresponds to N^{α}-acetyl-3-hydroxykynurenine. This is based on a comparison of the R_F values, colour reactions, and absorption spectra of spots *F* and *J* (kynurenine and its acetyl derivative) and spots *E* (hydroxykynurenine) and *I* (its postulated acetyl derivative) and is supported by the result of the above experiment (Fig. 2).

N^{α}-Acetylkynurenine has been previously isolated from a mutant strain of Neurospora[14]. The presence in urine of acetyl derivatives of normal metabolites is of some interest; but the significance of the finding cannot as yet be readily assessed.

The identity of the remaining unknown spots is at present being investigated. The following could not be detected on the chromatograms: oxindolylalanine, N^{α}-acetyltryptophan, anthranilic acid, 3-hydroxyanthranilic acid, acetylanthranilic acid, indole, skatole, indole acetic acid, indole propionic acid, indole pyruvic acid, tryptamine, *o*-aminoacetophenone, nicotinic acid, nicotinamide, nicotinamide methochloride, or quinolinic acid. Treatment of the urine preparations with formylase[5] showed no increase in kynurenine, and therefore the absence of formylkynurenine; this is to be expected owing to the ready hydrolysis of the formyl group.

Kynureninase and Pyridoxine in Tryptophan Metabolism

An enzyme in liver, kynureninase, was described by Kotake and Nakayama[15] and further studied by Wiss[16], who showed that the reaction was specific for L-kynurenine, and formed anthranilic acid and alanine. The work of Braunshtein *et al.*[17] demonstrated that the kynureninase activity was decreased in pyridoxine deficiency, and that the enzyme required pyridoxal phosphate. The possibility that the interruption of this reaction in pyridoxine-deficiency produced the abnormal accumulation of tryptophan metabolites prompted us to investigate it further.

The activity of kynureninase in liver is low, comparable to that of the tryptophan peroxidase[5], and only about 10 μmol. of kynurenine react per gm. liver (dry wt.) per hr. The long (20 hr.) reaction periods mostly used by previous investigators can be replaced

R296

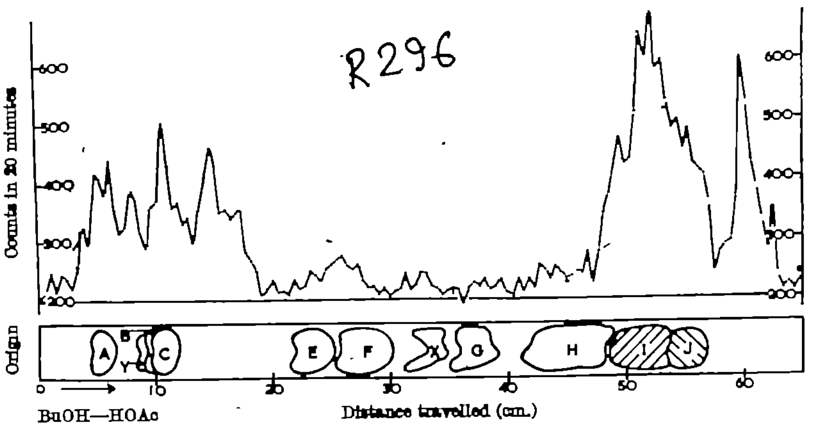

Fig. 2. Comparison of radioactivity and location of fluorescent spots on a chromatogram obtained after simultaneous feeding of tryptophan and ^{14}C-labelled acetate to a pyridoxine-deficient rat. Spot *Y* is a 'pigment' spot, not derived from tryptophan

TABLE 1. EFFECT OF PYRIDOXINE ON KYNURENINASE ACTIVITY *in vivo* AND *in vitro*

0·5 ml. of rat liver enzyme preparation plus 1·0 μmol. L-kynurenine and 0·1 ml. 0·2 *M*-borate, *p*H 8·0, in a total volume of 1·2 ml. Pyridoxal phosphate added as indicated. Deproteinized with 4 ml. of ethanol after 40 min., incubation at 38°. Initial and final determinations of kynurenine in the reaction mixtures were calculated from the absorptions at 365 mμ minus the absorptions of controls containing no kynurenine

Enzyme preparation	Pyridoxal phosphate added μgm.	Kynurenine μmol./gm. dry wt.	Disappearance μmol./ml.
Homogenates, normal rats	0	9·6 (12 animals)	
,, pyridoxine-deficient rats	0	2·7 (2 animals)	
Supernatant, dialysed (normal rats)	0		0·37
Supernatant, dialysed (normal rats)	10		0·49
Ethanol precipitated	0		0·46
,, ,,	10		0·60

Precipitated with ethanol and ammon. sulphate	10		0·44

by short-term experiments using more sensitive methods. We have measured the disappearance of kynurenine by the decrease in absorption at 365 mμ. Under our conditions (Table 1), the amount of kynurenine disappearing is proportional to time and to the amount of enzyme present. From the increased absorption at 310 and 330 mμ, in the same solution, can be calculated the amount of anthranilic acid and the small amount of kynurenic acid formed by the reaction. The products, alanine, anthranilic acid and kynurenic acid, have been identified by paper chromatography. Approximately twenty-fold purification of the enzyme in a liver homogenate has been obtained by the removal of insoluble material at *p*H 5, followed by ethanol and by ammonium sulphate fractionations. The enzyme from normal rats has been partially resolved by treatment with ammonium sulphate and shown to require pyridoxal phosphate as coenzyme (Table 1). The kynureninase activity was markedly decreased in pyridoxine-deficient rats. These findings confirm those of Braunshtein *et al.*

The purified kynureninase preparation also splits hydroxykynurenine to analogous products and at roughly the same rate as L-kynurenine (compare ref. 18). Acetylkynurenine, however, is acted upon only after it is hydrolysed to kynurenine by a deacetylase present in liver and still not completely separated from our best preparations of kynureninase.

These actions of kynureninase, dependent upon pyridoxine, could account for the accumulation of kynurenine and hydroxykynurenine in pyridoxine-deficient rats given tryptophan. Of additional interest is the persistent formation of small amounts of the quinoline carboxylic acids, apparently by the same reaction. Approximately the same proportion of total degraded kynurenine goes to form kynurenic acid by the action of either crude or purified enzyme. Furthermore, it was found that the amount of kynurenic acid formed could be increased by the addition of excess pyruvate to the reaction, without a comparable increase in the total kynurenine disappearing. The degree of increase possible in this way was similar in both crude and purified enzymes (Table 2). The lack of summation and the parallelism with crude and purified enzymes in yields of the two aromatic products derived from kynurenine suggest that kynurenic acid is a by-product of the same set of reactions which form anthranilic acid and alanine from kynurenine.

TABLE 2. KYNURENIC ACID FORMATION AS A BY-PRODUCT IN THE KYNURENINASE REACTION

Experimental conditions as in Table 1, with the addition of 10 μmol. of lithium pyruvate as indicated

Enzyme preparation	Kynurenine disappearance μmol.	Kynurenic acid formed μmol.
1. Crude liver supernate	0·49	0·06
,, ,, ,, +pyruvate	0·53	0·13
2. Ammon. sulphate fraction	0·57	0·01
,, ,, +pyruvate	0·62	0·16
3. Ethanol and ammon. sulphate fraction	0·90	0·33
,, ,, ,, +pyruvate	0·88	0·67

The mechanism of the kynureninase reaction has not yet been elucidated. The possibility that alanine is formed from kynurenine by two transamination reactions, in the way that alanine arises during tyrosine metabolism[19], is excluded by the finding that neither the addition of α-ketoglutarate nor of pyruvate is necessary for the reaction, even in the most purified preparations. These experiments did, however, reveal the effect of pyruvate, and to a lesser extent that of α-ketoglutarate, in increasing the proportion of kynurenine going to kynurenic acid. If kynurenic acid is formed as a by-product of the main kynurenine reaction this would be indirect evidence for an intermediate deamination of kynurenine to an α-keto acid, as opposed to the direct fission of kynurenine. The mechanism would involve the formation of the α-keto acid corresponding to kynurenine and its hydrolysis to anthranilic acid and pyruvate. The deamination of kynurenine to its keto acid, and the reamination of the pyruvyl fragment to form alanine, could occur through a cyclic transamination of the coenzyme for the reaction, pyridoxal phosphate. Excess pyruvate would then hasten the regeneration of pyridoxal phosphate, and increase the deamination of kynurenine. Some of the unstable keto acid accumulating under these conditions would form kynurenic acid by ring closure before it could be hydrolysed.

We are greatly indebted to Prof. A. Butenandt for a specimen of synthetic hydroxykynurenine and for making available to us prior to publication the paper by Dr. H. Hellmann, and to Dr. W. W. Umbreit for a gift of pyridoxal phosphate.

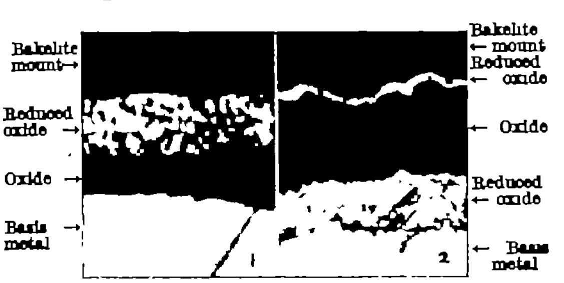
REDUCTION OF FERROUS OXIDE

By O. H. GELLNER and Dr. F. D. RICHARDSON

Nuffield Research Group in Extraction Metallurgy, Royal School of Mines, South Kensington, S.W.7

SINCE most of the previous research on the reduction of iron oxides has been carried out on ores and other poorly controlled and impure materials, we started some time ago on a systematic investigation of the reduction of the oxides of iron. So far the investigation has only properly covered the reduction of polycrystalline layers of wüstite—the non-stoichiometric ferrous oxide approximating to the composition $Fe_{0.95}O$ when in equilibrium with iron. These were prepared on polycrystalline strips of Swedish iron. The impurities in this metal totalled 0·3 per cent, of which 0·15 per cent was manganese and 0·04 per cent tungsten. Although not complete, the results so far obtained are of considerable interest. The work is being continued and it is intended to publish a full report elsewhere at a later date.

Layers of wüstite approximately 10^{-2} mm. thick were prepared by passing controlled mixtures of hydrogen and water vapour over strips of the iron at 900° and 950° C. The layers were then reduced in hydrogen at temperatures ranging from 600° to 1,000° C. The kinetics of the reduction were studied by collecting and weighing the water produced, and the mechanisms followed by microscopic examination. Reduction of the specimens could be arrested at any desired stage by drawing them into a cool part of the furnace, where they were rapidly quenched to room temperature.



Wüstite layer on iron partially reduced at (1) 700° C. (× 850) (2) 950° C. (× 650)

Photomicrographs of cross-sections of two typical specimens after partial reduction are shown. At 700° C. (Fig. 1) reduction of the wustite layer proceeds, as would be expected, from the surface inwards, a spongy layer of iron being produced. At 900° C. and above (Fig. 2) a very thin film of iron first forms on the oxide surface; but its growth soon ceases. Virtually all the reduction then proceeds outwards from the interface where the basis metal meets the oxide layer. At intermediate temperatures reduction proceeds simultaneously inwards from the surface and outwards from the metal. The results with different specimens at each temperature were consistent and reproducible.

One would have expected that reduction at all temperatures would have proceeded from the surface inwards. The fact that it proceeds outwards at the higher temperatures indicates that layers of wüstite grown under our conditions have some unexpected properties.

It appears to us that the most simple explanation consistent with all the facts is that the oxide in the immediate neighbourhood of the basis metal is less stable than the oxide on the surface and that there is a gradation of stability across the layer. This might be due, for example, to strain, which has commonly been shown to occur in oxide films[1], and which might be expected to decrease gradually with distance from the metal. On this hypothesis the course of reduction would be as follows: (1) removal of oxygen by hydrogen from the surface of the oxide with resultant supersaturation of the oxide with iron; (2) nucleation of this excess iron to form a thin layer of massive metal on the surface; (3) retardation of further reduction by the surface metal, which restricts access of hydrogen to the oxide and the diffusion of water vapour away from it; (4) diffusion of the excess iron, produced in the outermost layers of oxide by the continuing reduction, into the body of the oxide; (5) when the temperature is high enough and the diffusion rapid enough, preferential growth of massive iron outwards from the basis metal, where the oxide is least stable.

Steps (1)–(3) inclusive are clearly operative at all temperatures and their mechanisms do not need further discussion here. Step (4) might take place both by movement of excess iron atoms towards the basis metal via the vacant iron lattice sites normally present in wüstite (about 5 per cent in equilibrium with massive iron) and by movement of oxygen atoms towards the surface to fill the vacant oxygen sites produced at the surface by the reduction.

Either diffusion process would be expected to have a high activation energy and hence a high temperature coefficient. For an activation energy of 50 k.cal., for example, the diffusion coefficient could increase 85-fold between 700° and 900° C. Diffusion could therefore bring about concentration gradients of excess iron across the oxide layer which change markedly with temperature, and might reasonably have the forms represented diagrammatically in Fig. 3. The more stable oxide should require a greater supersaturation with excess iron than the less stable, before massive iron can grow continuously from it. If these supersaturation limits (c_1 and c_2) are as illustrated in Fig. 3 relative to the concentration gradients of the excess iron, the results obtained in practice would automatically follow.

In conformity with this theory we found that the course of reduction was independent of whether the oxide layers were prepared and reduced above or below the α–γ transformation temperature in iron (910° C.), or whether the substrate metal was oxidized completely away. In addition, we have found that if a completely oxidized specimen is annealed for a sufficiently long period to produce recrystallization,

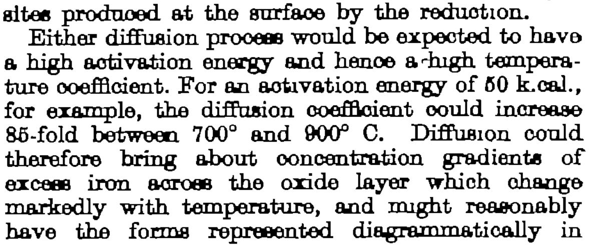


Fig. 3. Schematic representation of concentration gradients (full lines) of excess iron across the oxide layer at (a) 700° C., (b) 800° C. and (c) 900° C. c_1 and c_2 represent the super-saturation limits required for growth of massive iron at the oxide surface and the oxide–basis metal interface respectively. The broken lines suggest how these limits may vary across the layer

the grains of oxide are then reduced more or less uniformly over their entire surfaces and there is no difference in behaviour between the material near the surface and that near the centre of the strip.

Since the first layers of wüstite formed initially on iron appear to be less stable than the massive oxide, their formation must require a higher oxygen potential than equilibrium between bulk phases of metal and oxide would indicate. The phenomenon represents a new type of passivity which may well vitiate equilibrium measurements involving formation of very small quantities of a new phase on a bulk substrate. It may account for the discrepancies reported in studies of the equilibria between solid iron and liquid and solid wüstite, in carbon monoxide–dioxide and hydrogen–steam gas mixtures[2-4]. These equilibria have been studied under conditions where solid iron is just oxidized, so that in cases where the oxide formed is solid the oxygen pressure will be higher than that for the bulk phase. When the product is liquid, no such passivity should occur, so that the equilibrium oxygen pressure will be lower than the solid results would indicate, when allowance is made for the change in state. This effect may also account for the unexpected passivity reported by Chipman and Marshall[2] when treating solid iron specimens under conditions which were just oxidizing.

The work reported here was done in the Chemistry Laboratories of the British Iron and Steel Research Association while we were members of the staff of that Association. [Jan. 9.

X-RAY SHADOW MICROSCOPE

By DR. V. E. COSSLETT and W. C. NIXON

Cavendish Laboratory, Cambridge

THE advantages of the short wave-length of X-rays may be exploited for microscopy by projecting shadowgraphs from a point source[1], the resolving power being then limited primarily by the size of the source. Electron lenses can be used for focusing the exciting beam so as to produce a point source of X-rays of very small dimensions[2]. The specimen may be kept in atmospheric conditions, and yet brought close enough to the source to give a high working magnification, if the target is in the form of a Lenard window and the transmitted X-rays are utilized[3]. The system is shown schematically in Fig. 1, where an electron lens L focuses the beam issuing from a cathode C on to the target T. An enlarged shadow of an object O is thrown on to a fluorescent screen or photographic plate S. Such an arrangement is capable of much higher magnification and resolution than the procedure adopted by Goby, Dauvillier, Engström and others[4], in which the specimen is almost in contact with the recording plate and is illuminated by a distant source of X-rays of normal size. In that case the limiting factor is the grain of the photographic emulsion, and a resolution of better than 10 microns is difficult to obtain. On the other hand, the point source is in principle limited in size only by the aberrations of the electron lens and could be made smaller than 100 A.; the exposure-time would then become in practice the limiting factor.

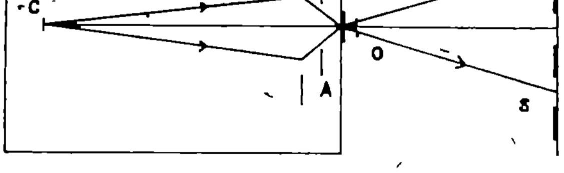

Fig. 1. Principle of X-ray shadow microscope

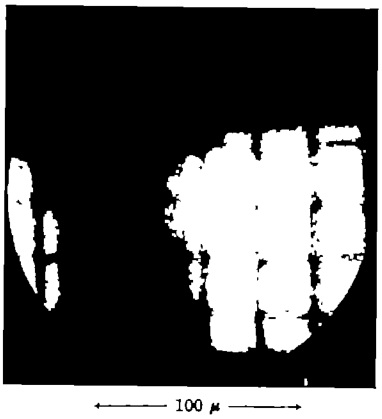

Fig. 2. X-ray shadowgraph of silver grid (1,000 mesh/in.) overlapping copper grid (200 mesh/in.) Original magnification, ×95; final magnification, ×285

An X-ray shadow microscope has now been developed, using a magnetic lens to demagnify the electron beam. The size of the spot obtained is of the order of 1 micron, when an aperture A is placed before the target to limit the electron beam and thus reduce the effect of lens aberrations. Accelerating voltages between 3 and 12 kV. have been employed, corresponding to X-ray wave-lengths of 1–4 A. The camera length is variable from 2 to 5 cm. or longer. Test results are shown in Figs. 2 and 3, taken at 10 kV. Fig. 2 shows a silver grid of 1,000 meshes to the inch carried on a 200-mesh/inch copper grid, the wires of the former being 5 microns in width; exposure time was 20 sec., primary magnification ×95. Fig. 3 shows a book louse (*Liposcelis granicola*) and part of a 1,500-mesh grid; exposure time 5 min., primary magnification ×25. As the 1,500-mesh grid is made of wires of 3 microns in diameter, the resolving power can be estimated to be of the order of 1 micron. The fine structures in the leg running across the bottom of Fig. 3 appear to be still thinner.

It appears that the resolution obtainable with a single stage of demagnification of the electron spot cannot, with existing electron lenses, much exceed 1 micron. The employment of two stages of demagnification raises no practical difficulty, but would seem to lack suitable biological specimens, owing to their low absorption of X-rays; it might be of more value for metallurgical investigations. In order to increase absorption, a lower accelerating voltage and correspondingly longer X-ray wave-length could be employed; but a vacuum camera would then be

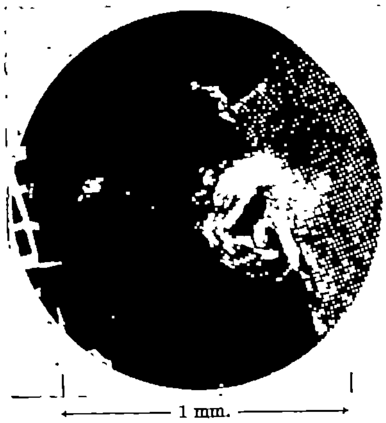

Fig. 3. X-ray shadowgraph of book louse (*Liposcelis granicola*) and silver grid of 1,500 mesh/in. Original magnification, ×25. final magnification, ×37

needed and the advantage of the specimen being in air would be lost.

The apparatus described, a fuller account of which will appear elsewhere, can also be used as a fine-focus tube for X-ray analysis. Indeed, the use of a magnetic lens is similar to that in the diffraction tubes devised by Goldsztaub[5] and by Witty and Wood[6]. It gives a much smaller spot than the fine-focus diffraction tube of Ehrenberg and Spear[7], which makes the maximum use of the electrostatic focusing action of the electron gun but employs no subsequent lens.

Thanks are due to D. A. Taylor and S. S. D. Jones, who assisted in the preliminary experiments. One of us (V. E. C.) has been supported by a Keddey Fletcher-Warr Research Studentship of the University of London (at the Electrical Laboratory, Oxford, 1939–41) and by an I.C.I. Research Fellowship (at Cambridge, 1946–49), and the other (W. C. N.) by a Scholarship of the Research Council of Ontario.

EMPIRE COTTON GROWING CORPORATION, 1921–50

A SHORT history of the Empire Cotton Growing Corporation, 1921–50, originally published in the *Empire Cotton Growing Review* of January 1951, is now available as a pamphlet. It includes a number of matters of scientific interest. The Corporation was incorporated by Royal Charter on November 1, 1921, as a result of the report of the Board of Trade's Empire Cotton Growing Committee in 1920, and was financed partly by a capital grant from the Imperial Government and partly by a levy on all raw cotton spun into yarn in the United Kingdom. Since the repeal of the Cotton Industry Act on March 31, 1948, the Corporation has received an annual grant of £18,000 from the Cotton Board.

Resembling in many ways a research association, the Corporation has concentrated mainly upon production, with its relevant agricultural and scientific problems and requirements. A first step was the training and enlistment of a scientific staff, and in this, since 1922, the Corporation has been in close association with the Imperial College of Tropical Agriculture in Trinidad. Relations established with the Shirley Institute at Manchester, by enabling plant-breeders to test new cottons at a much earlier stage, have led to a great saving of time, land and labour. Another early step was to enlist the help of scientific experts in general agriculture, soil science, genetics and plant breeding, plant physiology, entomology and plant pathology, and particular tribute is paid to the services of the late Sir John Farmer.

The agricultural and scientific policy of the Corporation has fully recognized that cotton-growing, to be permanent, must be associated with other crops in the general system of agriculture of the countries concerned. A Research Station was established in Trinidad in 1926 and closed at the end of 1944, when it was decided that the next phase of the work could more advantageously be carried out in a country producing a commercial cotton crop. A site for the new Station was found at Namulonge, Uganda, and of the estimated capital cost of £206,500 half was provided from Colonial Development and Welfare Funds, £78,250 from the Corporation's invested resources, and £25,000 from the Cotton Industry War Memorial Trust. The Corporation is to find £170,000 of the recurrent expenditure, estimated at £400,000 over the ten years from October 1, 1947, Colonial Development and Welfare Funds are providing £100,000 and the Governments of Uganda, Tanganyika, Nigeria, Kenya and Nyasaland, jointly, have promised £130,000. The Uganda climate has necessitated stationing the Cytogenetics Section at Shambat, near Khartoum. Figures are quoted to demonstrate, on the basis of record crops, the capacity of the Empire to grow more than a million bales of cotton per annum; and three-year averages show that production in the Anglo-Egyptian Sudan has increased from 23,225 bales in 1918–21 to 299,872 in 1946–49; in Uganda from 55,196 to 262,929; in Kenya from 233 to 6,574 bales; and in Tanganyika from 2,442 to 48,345 bales, for the same periods.

SOUTH-EASTERN UNION OF SCIENTIFIC SOCIETIES

ANNUAL CONGRESS

AT the invitation of the Camberley and District Natural History Society, the South-Eastern Union of Scientific Societies held its fifty-sixth annual congress at Camberley during April 26–29 under the presidency of David Seth-Smith. The local committee for the congress was under the chairmanship of Major Maxwell Knight, with Miss Jean Armitage as local secretary.

At the 'young naturalists' evening', Dr. W. E. Swinton, of the British Museum (Natural History), lectured on "Prehistoric Reptiles", illustrating his remarks with lantern slides and films. A Nature quiz competition took place between teams from the junior section of the Natural History Society and the local schools. The junior section also largely contributed to the success of an excellent nature-study exhibition by displaying specimens, examples of their field-work, notebooks and drawings.

The presidential address to the Zoological Section was given by Sir Philip Manson-Bahr, who spoke on "The Contribution of Zoology to Medicine". He dealt with the early investigations into the causes of elephantiasis and malaria and with subsequent work upon the life-cycles of the insects responsible for these and other diseases. A. J. Low gave the presidential address to the Geological Section and conducted an excursion to the Jealott's Hill Research Station of Imperial Chemical Industries, Ltd., where he demonstrated some of the points of his address dealing with soil fertility, the influence of leys, microlysimeters and soil profiles,

Mr. Seth-Smith's presidential address to the Union was on "Man's Control of Wild Animals". He commenced by saying that there are people who think that zoological gardens should not be allowed to exist, as it is cruel to confine any wild animal. Such people invariably say they do not visit the zoo because they do not approve of it. Mr. Seth-Smith said that he has always been fond of animals and so of zoos, for there one can see animals which one could never hope to see in a wild state, can study their forms and actions, and know them individually and intimately. All domesticated animals were derived from wild species, and the world is now dependent upon them for its very existence. The camel was domesticated so long ago that it is not known where its wild home was. Job possessed six thousand of them, so that they were domesticated before his time. In England the first real zoological gardens was established by Henry I at Woodstock in Oxfordshire; it was removed to the Tower of London by Henry III and was transferred to Regent's Park, London, on the formation of the Zoological Society in 1829. Zoos are of the greatest educational value, for though the student can read about animals and see their stuffed skins in museums, it is not until he observes them in the wild or in captivity that he acquires a true idea of their living form.

Dealing with the problem of how do animals feel about being in a zoo, Mr. Seth-Smith said his thirty years of experience as curator led him to think that the majority, if capable of choosing, would vote for a safe and comfortable home in captivity. Most animals in a zoo are born there or are brought in from the wilds when quite small babies. Most wild animals have their own areas in which they live, and in captivity they regard their enclosures as their territories and apparently are not particular as to their size. Scientific experts are employed to ensure the health and happiness of the animals. As an example, almost every wild animal suffers from internal parasites. The very first thing at a zoo with a new arrival is thorough examination for, and treatment of, these pests. Very few wild animals die of old age or sickness. The majority are preyed upon, while the predators when old or infirm either die of starvation or are themselves killed. In zoos they live their full lives, the span of which is longer than their chances in a native haunt. Man is the greatest enemy of all wild life; his greed, cruelty and ignorance are leading to its extermination even to-day. Wild animals are afraid of man when taken under his control; but when well treated, well fed and safe from enemies, they soon become reconciled and regard man as their protector. Some animals have been saved from total extinction by being taken into zoos and collections. Were it not for zoological gardens we should have a poor idea of the wonderful animals that share the earth with us and should have to rely chiefly upon the stories of hunters, whose chief idea was perhaps to magnify the danger in their destruction.

Other events that took place at the meeting are, briefly, as follows. Prof. F. W. Jane, as president of the Botanical Section, spoke on "Trees and Scenery", and H. H. Coghlan chose for his presidential address to the Archæological Section the theme "Aspects of Prehistoric Metallurgy in Southern England". Excursions were conducted to Frensham Pond and Haslemere Museum with Major Maxwell Knight and Francis Rose as leaders. C. D. Ovey described aspects of weather and weather forecasting, showing 'Kodachrome' slides of features of meteorological interest. He stressed the importance of relating scientific observations with those of the field naturalist and the farmer. At the general assembly the methods of developing the usefulness of the Union to its affiliated societies was discussed at length and a sub-committee appointed to formulate schemes for that purpose.

SOUTH-WESTERN NATURALISTS' UNION

ANNUAL CONFERENCE

THE South-Western Naturalists' Union held its 1951 annual Whitsuntide conference (the twenty-fourth) during May 11–14 at Taunton as guests of the Somerset Archæological and Natural History Society. It was to this Society, and particularly to the hard work of the local secretary, A. D. Hallam, in planning the programme, that the success of the conference was largely due.

A reception was held by the Mayor, Councillor W. F. Heywood, at the Municipal Buildings on the evening of May 11, and then on the following day nearly sixty members visited the Blackdown Hills under the leadership of Mr. and Mrs. Hallam. Halts were made at Priors Park Wood, Britty Common, Castle Neroche and Ashill Church. At Priors Park Wood, where many birds, including the nightingale, were heard and where several badger setts were seen, the attention of the botanists was directed to the marked influence that changes in the geological formation had upon the vegetation. On Britty Common exposures of the Upper Greensand and overlying gravels were examined by the party. H. St. George Gray conducted the party over the earthworks of Norman date known as Castle Neroche, and the interesting features of Ashill Church were explained by Mr. Hallam. In the evening, W. A. Seaby lectured on Ham Hill, where many important finds of late Iron Age and Roman date have been made; the talk was amply illustrated by lantern slides.

Most of May 13 was taken up by an excursion to the region around Minehead. In the morning, Porlock Marsh was explored, under the guidance of H. G. Hadden, for plants and animal life; and members visited the village of Bossington, after which they drove to Horner Woods and from there to Minehead. After tea the party divided; one half visited Cleeve

Abbey, which was described by Mr. Seaby, and the other half, the cliffs at Watchet, where the Keuper and Lower Lias are well exposed. The geology was explained by Mr. Hallam and Dr. Stanley Smith. In he evening Peter Scott, president of the Union, delivered his address; he explained two coloured films, one of bird life in northern Europe taken during his visit to Scandinavia in 1950, and the other illustrating experiments in netting wild geese for the purpose of ringing. In this work, nets are carried over the flock after it has settled, by means of rockets electrically exploded.

The final morning was occupied by the council and general meetings, with A. O. Rowden presiding over both. In the course of his remarks at the general meeting, Mr. Rowden alluded to the recent public enquiry into the use by the military of Braunton Burrows and to the matter of footpaths. The secretary reported that the South Western Naturalists' Union embraces at the present time twenty-one affiliated societies or sections of societies.

SILTING IN BRITISH RESERVOIRS

By R. M. PROTHERO

ARTICLES in previous issues of *Nature*[1] have stressed the need for the proper study of the relationship between rainfall and run-off in Britain, since its influence in promoting soil erosion, dependent on the vegetation cover and on the soil cover itself, may be more considerable than we imagine. There is the danger that because of the lack of spectacular examples of soil erosion such as occur in other parts of the world, we may ignore it and fail to realize its presence. As a result of this attitude, precise information is practically non-existent and it is necessary to rely on evidence which is fragmentary in nature and which has often been collected only incidentally.

Important evidence relating to the removal of soil by heavy rainfall is provided by information on the silting, caused by the deposition of this material, of British reservoirs. A survey, covering twenty-eight of the major water-undertakings in Britain, revealed in the first place an absence of any co-ordinated information. An attempt to survey the floor of a reservoir in the Tâf Fawr valley, Breconshire, during the drought of 1949 was unfortunately unsuccessful owing to the onset of rain. This would undoubtedly have provided important and precise evidence as to the rate of silting in that area.

It is possible to prevent the transport of material of large size into reservoirs by the construction of catch-pits and wreck-lodges in the tributary streams. To prevent the entry of finer material, carried in suspension during periods of high stream flow, is a more difficult problem. Such material, deposited on the floor of a reservoir, may accumulate in a short time and seriously reduce its capacity. In Great Britain examples are not so outstanding as in the United States, where in 1934 the Soil Conservation Service reported that in a survey of fifty-six reservoirs, it was found that thirteen major dams, with an average height of 30 ft., had silted up completely during an average life of twenty-nine years.

The most outstanding example in Britain known to me, of nearly a 50 per cent reduction in capacity in seventy-eight years, has already been quoted in a previous article[2]. Rates of silting vary considerably: from an accumulation during a hundred years of 6 ft. of silt on the floor of a reservoir with an area of 40 acres and an average depth of 25 ft. at the time of construction; to 6 in. accumulated over a 44-year period. In many of the reservoirs there is no marked silting at all, but in eleven out of the twenty-eight undertakings for which information was received it will become serious within the next hundred years. But even if the rate of silting is slow, we must take a long-term view of our facilities for providing water, remembering that demands on available supplies are steadily increasing. In four reservoirs built in 1798, 1830, 1876 and 1880, capacity has been reduced by 12, 12, 5·5 and 8 per cent respectively; but the situation will become serious only if an increased demand exceeds the surplus available at the present time. In such circumstances the engineer reported that it would be more practical to increase capacity by raising the top-water-level of the reservoirs rather than to attempt to remove the silt. In only one instance was there an actual reference to allowance being made for reduction in capacity by silting at the time of the construction of the undertaking. The allowance was for a 20-million gallon reduction in the case of one reservoir and of 10 million gallons each for the other two. But though allowance had been made for reduction in total capacity, several hundred tons of silt had to be removed from around the draw-off tunnel of one of the reservoirs in 1933.

The problem of silting does not appear to have been allowed for in the calculated capacities of the reservoirs now being constructed as an integral part of the hydro-electric power schemes in the Scottish Highlands. In fact, the possibility of the problem arising does not seem to have been considered. A recent article on the developments taking place[3] stated that, in addition to the influence they would exert on flood control, "The reservoirs will also act as traps for sand and silt which at the present time are washed down to the sea and in many places, particularly on the north-east coast, have filled up estuaries and harbours".

While acknowledging the benefit to Scottish harbours, it must be pointed out that this will only be attained at the expense of creating a problem in the reservoirs themselves. The dredging of a harbour would appear to be a much simpler operation than the removal of silt from a reservoir, quite apart from the interference with water supply to the turbines entailed in carrying it out.

Silting is most marked where erosion, particularly by gullying in the beds of the streams feeding the reservoirs, takes place in deposits of sand and peat. It is also a feature where glacial till, widespread in the north and west of Britain, is being eroded. In being complementary to erosion, silting is the most significant evidence available of the existence of the former. Even if silting may not become a serious problem for a hundred years or more, the time to take action to prevent it is at the present. The remedial measures necessary have been stated in previous articles; but in order that they may be planned to produce the maximum effect it is essential that a considerable body of accurate information be accumulated on the related factors of rainfall, run-off, erosion and silting.

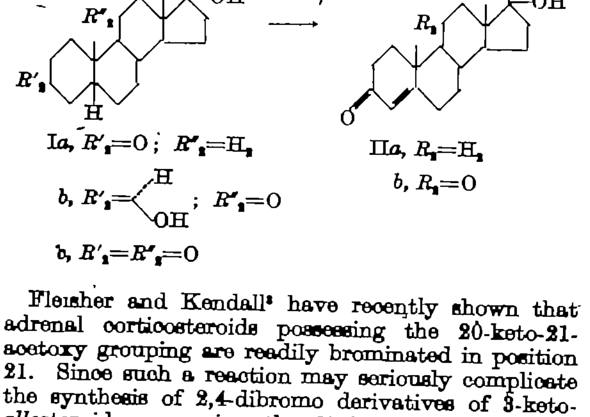
Cortical Hormones from *allo*Steroids: Synthesis of Cortisone from Reichstein's Compound *D*

Cortisone acetate (II*b*) has so far only been synthesized[1] from bile acids which possess the 'normal' configuration at C-5 (rings *A*/*B* *cis*). Since the potentially most abundant sources, such as the steroidal sapogenins, belong to the *allo* series (rings *A*/*B* *trans*) or are readily convertible to the latter, it is important to accomplish the transformation of an *allo*steroid to cortisone. We have recently described[2] a method for the conversion of 3-keto-*allo*steroids into Δ^4-3-ketones, which involved dibromination to a 2,4-dibromo derivative, treatment of the latter with sodium iodide in acetone solution to yield a 2-iodo-Δ^4-3-ketone and subsequent de-iodination with chromous chloride, collidine or zinc. This procedure was applied successfully in the androstane, etio*allo*cholanic acid and *allo*pregnane series. The usefulness of this method for the important 17,21-dihydroxy-20-keto steroids remained to be demonstrated.



I*a*, $R'_3{=}O$; $R''_{11}{=}H_2$

b, $R'_3{=}{<}^{H}_{OH}$; $R''_{11}{=}O$

b, $R'_3{=}R''_{11}{=}O$

II*a*, $R_{11}{=}H_2$

b, $R_{11}{=}O$

Fleisher and Kendall[3] have recently shown that adrenal corticosteroids possessing the 20-keto-21-acetoxy grouping are readily brominated in position 21. Since such a reaction may seriously complicate the synthesis of 2,4-dibromo derivatives of 3-keto-*allo*steroids possessing the 17,21-dihydroxy-20-keto side-chain, we have examined the sodium iodide method[2] in the case of *allo*pregnane-3,20-dione-17α,21-diol 21-acetate (I*a*)[4]. The ketone I*a* was treated at 16° in chloroform – acetic acid solution with two moles of bromine, a small amount of anhydrous hydrogen bromide in acetic acid was added to facilitate the rearrangement of the presumable[5] initial 2,2-dibromo compound to the 2,4-isomer, and after twenty hours the chloroform solution was washed free of acid and evaporated to dryness *in vacuo*. The crude 2,4-dibromo derivative was not crystallized, but was refluxed immediately with an excess of sodium iodide in acetone solution for twenty hours. After concentrating, extracting with ether, washing with thiosulphate solution and evaporating to dryness, the residue was refluxed for half an hour in dioxane solution with 5 per cent sodium bisulphite solution. This latter de-iodination procedure proved particularly suitable for adrenal hormones of type II.

Dilution with water, filtration and recrystallization from acetone afforded Δ^4-pregnene-3,20-dione-17α,21-diol 21-acetate (II*a*) (Reichstein's compound *S* acetate) of melting point 233–235° (all melting points are uncorrected), $[\alpha]_D^{20}$ + 109° (acetone), ultra-violet absorption maximum (95 per cent ethanol) at 240 mμ (log ε, 4·36). This represents the third synthesis of Reichstein's compound *S* from readily available pregnane derivatives[6].

The synthesis of *allo*pregnane-3β,17α,21-triol-11,20-dione 21-acetate (I*b*) (Reichstein's compound *D* mono-acetate) was recently accomplished in this laboratory[7] from *allo*pregnane-11,20-dione-3β-ol, which in turn was obtained from a number of steroidal sapogenins. I*b* had a melting point of 235–237°, $[\alpha]_D^{20}$ + 66° (acetone) (calc. for $C_{23}H_{34}O_6$: C, 67·95; H, 8·43; found: C, 68·22; H, 8·73), and was correlated with Reichstein's compound *D*[8] via the 3,21-diacetate (m.p. 220°)[9]. Oxidation of I*b* with N-bromoacetamide in pyridine solution afforded *allo*pregnane-3,11,20-trione-17α,21-diol 21-acetate (I*c*), of melting point 235–237°, $[\alpha]_D^{20}$ + 78° (acetone), + 89° (chloroform) (calc. for $C_{23}H_{32}O_6$: C, 68·29; H, 7·98; found: C, 68·13; H, 7·63). Dibromination in acetic acid solution (without chloroform), as described above for I*a*, followed by dilution with water, produced a solid dibromo derivative (m.p. 150–153° (dec.); calc. for $C_{23}H_{30}O_6Br_2$: Br, 28·42; found: Br, 28·67) which without purification was carried through the sodium iodide and sodium bisulphite steps as described above. Passage of the final product through a short column of ethyl acetate-washed alumina and two recrystallizations from acetone of the benzene–ether eluates yielded colourless needles of Δ^4-pregnene-3,11,20-trione-17α,21-diol 21-acetate (II*b*) (cortisone acetate), of melting point 236–238°, $[\alpha]_D^{20}$ + 181° (acetone), ultra-violet absorption maximum at 238 mμ (log ε, 4·35). The infra-red spectrum (chloroform) was identical with that of an authentic specimen.

While the overall yield in the conversion of the ketones I*a* and I*c* to the adrenal hormones II was somewhat lower than observed earlier[2] in the androstane series, the present results clearly demonstrate the feasibility of synthesizing cortisone and other adrenal hormones from *allo*steroids of plant origin.

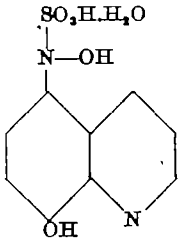
Antitubercular Activity of some 8-Hydroxyquinoline Derivatives

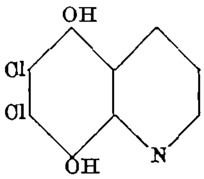
THE well-known antiseptic properties of 8-hydroxyquinoline, and particularly experiments on the use of this compound as an antitubercular agent[1], led one of us (T. U.) to prepare a few derivatives of 8-hydroxyquinoline, in order to examine their activity against *Mycobacterium tuberculosis*.

One of the products tested, *T* 28, proved to be particularly interesting due to its activity both *in vitro* and *in vivo* and to its low toxicity. The product was prepared by the action of sodium hydrogen sulphite on 5-nitroso-8-hydroxyquinoline. It proved to be monohydrate of N-sulpho-N-[5-quinolyl-8-hydroxy]-hydroxylamine (I), so far unknown in the literature.

A detailed description of the method of preparation and the proof of the structure will be reported elsewhere[2]. On boiling with concentrated hydrochloric acid, (I) was hydrolysed and, surprisingly enough, chlorinated, to yield the hydrochloride of 6.7-dichloro-5.8-dihydroxyquinoline (II).



I



II

The substance (II) also possesses strong antitubercular action *in vitro*, but experiments *in vivo* have not been carried out because of its high toxicity.

The other 8-hydroxyquinoline derivatives tested were: 5-amino-(III)- and 5.7-diamino-(IV)-quinoline. They were prepared in a new way—by reduction with sodium hydrosulphite of 5-nitroso- and 5.7-dinitro-8-hydroxyquinoline respectively. 5-Sulpho-8-hydroxyquinoline (sodium salt) (V) and 8-hydroxyquinoline sulphate (VI) were also tested and used as a standard.

The bacteriostatic concentrations were determined *in vitro* in Youmans's medium against six strains of saprophytic mycobacteria. Limits obtained for different strains are shown in Table 1.

Table 1

Substance	*T* 28 (I)	(II)	(III)	(IV)	(V)	(VI)
Bacteriostatic concentrations (mgm per 100 ml.)	5–30	2	2·5–5	2·5–15	125–250	2·5–5

Table 2 shows the toxicity to rats of substances (I)–(V).

Table 2. LETHAL DOSE (GM. PER KGM. BODY-WEIGHT)

Substance	Intravenous injection	Subcutaneous injection	*per os*
T 28 (I)	1·0	1·5	*c.* 3·0
(II)	0·02	—	—
(III)	0·06	0 11	*c.* 0·5
(IV)	0·02	0·03	0·5
(V)	1·2	2 0	*c* 5 0

The experiments carried out with Langendorf's rat's heart preparation showed that *T* 28 has no influence on the heart and coronary flow when 0·1 ml. of 5 per cent solution was administered. When given intravenously to a rabbit in doses of 50 mgm. per kgm. body-weight it caused only a small and temporary increase of the blood pressure. An injection of 50 mgm. per kgm. body-weight produced a fall of the sugar level by *c.* 20 per cent, lasting for 4 hr. Also only a very insignificant influence was observed on the peristaltic concentrations of the isolated rabbit's small intestine in a 0·1 per cent solution. No hæmolysis of rabbit red cells *in vitro* was observed.

Experiments *in vivo* were carried out by using guinea pigs (*c.* 500 gm.) inoculated intraperitoneally with 0·1 mgm. of *Mycobacterium tuberculosis* ($H_{37}Rv$ strain). The results are shown in Table 3.

Table 3

	No. of animals	Daily dose (mgm per animal, subcut.)	Mortality (per cent)	Average tuber. index	Average survival time (days)
Streptomycin	20	8	10	57	84·4
T 28	20	10	40	64	76·1
Control	20	—	90	100	47·2

Treatment with *T* 28 and streptomycin started one week after inoculation.

The animals were treated for 42 days. They were then observed for a further 36 days; all survivors were killed, and the extent of tuberculous involvement was noted and rated.

Experiments on the clinical use of *T* 28 are being commenced.

Preparation of the Optical Forms of Tris-Acetylacetone Cobalt III

IN an earlier communication[1], a number of experiments were described leading to the conclusion that the activities of enantiomeric ions could be changed to a different extent by the addition of an electrolyte containing an optically active anion or cation. In order to demonstrate the general applicability of this principle, we have sought to resolve a typical non-electrolytic complex salt without salt-forming groups The peripheral atoms in the tris-acetylacetone cobalt III complex probably carry a slight negative charge, and hence negative or anionic asymmetrical fields are associated with the antipodal forms. The maximum differential interaction in solution is to be expected with a multiply-charged optically active cation, and for the purpose *d*- and *l*-tris-ethylenediamine cobalt III iodides were used.

In the initial experiments, the acetylacetone cobalt complex was dissolved in 20 per cent chloroform in ether and extracted ten times with 2 per cent aqueous *d*-tris-ethylenediamine cobalt iodide, saturated with ether. The small portions dissolving in the aqueous layer were extracted completely with chloroform, which was then evaporated rapidly at room temperature. The small amount of green residue, in aqueous alcohol, was found to have a slight lævorotation.

In subsequent experiments, the acetylacetone complex (0·5 gm.) in 25 per cent aqueous alcohol (100 ml.), containing tris-ethylenediamine cobalt iodide (2 gm.), was heated to 60° C. for a few minutes, cooled to room temperature and allowed to stand for three days. The material that had separated (0·25 gm.) was found to be inactive. The filtrate cooled to 4° C. was fractionally treated with solid ammonium chloride to salt out the substance. The fractions, after washing with saturated ammonium chloride solution, were found to become increasingly lævorotatory. The most soluble fraction (0·03 per cent in 20 per cent aqueous alcohol) gave $\alpha = -0{\cdot}09°$. From this value, on a material probably not optically pure, $[\alpha]^{20}_{5461}$ is $-$ 300°. Similarly, with *l*-Co(en)$_3$I$_3$ the dextro form was obtained.

The rotation in the Na$_D$ line was very small. Most of the substance had racemized in solution after twelve hours; but the solid was still active after three days.

The failure to detect both antipodes in any experiment demonstrated that the separation had been achieved through a 'first-order asymmetrical transformation'. In the presence of the *d*-Co(en)$_3^{3+}$ ion, the activity of the *l*-form of the acetylacetone complex was depressed more than the *d*-enantiomer, and the equilibrium between the antipodes moved until the activities were equal, that is, until there was an excess of the lævo form. The first-order asymmetrical transformation could be observed with difficulty as a mutarotation, but was confirmed by the addition of *d*-Co(en)$_3$I$_3$ to an aqueous solution of the complex, and, after standing for three days, extracting it completely with chloroform. The 0·047 per cent solution in chloroform had $\alpha = -0{\cdot}07°$. This result shows that, contrary to the opinion of Turner and Harris[2], first-order transformations do not require direct chemical combination between the 'activating agent' and the centre being 'activated'.

The optical forms of tris-acetylacetone chromium III, obtained in the same manner, were more stable than the cobalt compound, while the iron III compound had a very fleeting life. It is possible that the separation of the chromium III antipodes involved both a solubility difference and an asymmetrical transformation.

The work is proceeding and will be published shortly. Our thanks are due to Dr. D. P. Mellor for suggesting the acetylacetone complexes as typical non-electrolytes.

Induction Periods in Reactions of N-Halogenimides

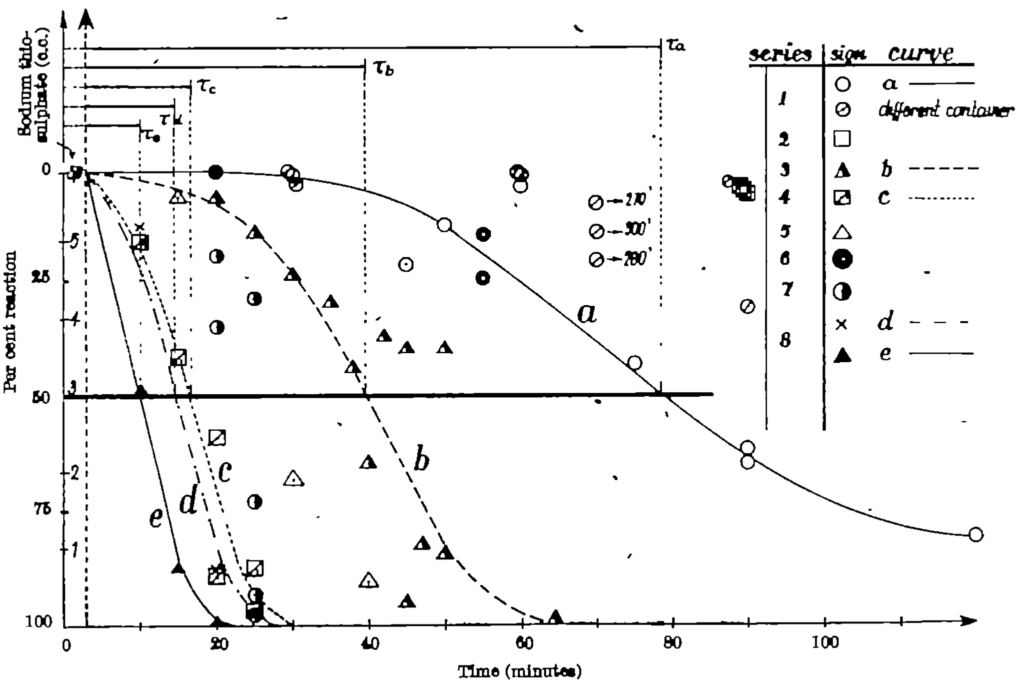
N-Halogenimides have been extensively used i preparative organic chemistry during the past fe years[1]. We have attempted to elucidate the mechanism of the reaction of N-chlorosuccinimide o toluene, in which the simplicity of the reagents an products appeared to be particularly suitable for suc a study.

On refluxing, in a quartz cell, a solution containin 0·08 mole of N-chlorosuccinimide per mole of toluen (b.p. 111°), we observed, in agreement with M Hebbelynck and R. H. Martin[2], who first studie this reaction, a rapid photochemical reaction; irradiation was carried out with a 125-watt medium-pressur mercury lamp ('Philora', Philips) at a distance o 10 cm., giving an effective intensity of about $5 \times 10^{-}$ einstein/min./sq.cm. By the use of uranyl oxalat actinometry[3], we found a quantum yield of the orde of 100 (the course of the reaction was followed by iodometry with *N*/10 sodium thiosulphate, i necessary following dilution with tetrachlorethane) At ordinary temperature, where the solubility limit the concentration to about 0·01 mole per mole o toluene, the quantum yield is of the order of unity. The photochemical reaction at ordinary temperature is of considerable interest, particularly in view o the fact that the photoactive component is toluene and not the N-chlorosuccinimide. It appeared necessary, however, to study first the *thermal reaction* at 110 ± 0·5° C. before attempting to interpret the quantum yield. Under conditions described above, but without irradiation, curve *a* shows the progress of the reaction as a function of time (series 1). Repetition of these experiments gave erratic results due to fortuitous conditions, such as the shape of the container used. But in all cases we noted induction periods at least as long as that illustrated in curve *a*, which should be considered as a limiting curve giving the maximum rate which is attainable under these conditions.

Considering the known inhibitory influence of oxygen on many halogenation reactions[4], we tried to degas the solution by passing oxygen-free nitrogen: this proved useless (series 2). We then carefully degassed the reagents under vacuum. After obtaining a gas pressure of less than 10^{-5} mm. mercury, at the temperature of liquid air, the bulbs containing about 4 c.c. of reaction mixture were sealed off under vacuum (series 3) and heated for varying times at 110° C. Under these conditions, curve *b*, which was very nicely reproducible, represents the course of the reaction. The half-reaction time falls from about 80 min. (τ_a) to 40 min. (τ_b).

Series 3 confirms the inhibitory effect of traces of oxygen, consumed during the initial phase of the reaction (induction period), and explains the erratic results obtained in the presence of air (series 1). Curve *b* still shows an induction period, even though its duration is markedly reduced.

We succeeded in nearly suppressing this induction period by means of a pre-treatment[5] (series 4, curve *c*, τ_c 17 min.). Bulbs containing N-chlorosuccinimide and toluene (prepared as for series 3) were heated during 180 min. and then broken under vacuum and their volatile constituents condensed on N-chlorosuccinimide in new bulbs. These new bulbs were then sealed off under vacuum and treated again as in series 3. Particular care was taken to eliminate all gases not condensed at liquid-air temperature.



The induction period in the experiments of series 3 could be due either to traces of impurities which are eliminated by the pre-treatment (series 4), or to the slow formation of a stable intermediate essential to the rapid progress of the reaction.

We confirmed the latter hypothesis by the following experiments :

(i) The effect of pre-treatment disappeared, at least partially (series 5), if the volatile constituents from pre-treatment are condensed by liquid air and then liquefied several times on a sodium mirror. Simultaneously we noted on the sodium the evolution of bubbles of a non-condensible gas equivalent to about 0·001–0·01 mole per mole of the N-chlorosuccinimide (pressure 10^{-1} to 10^{-3} mm. mercury in 1 litre). We assumed that it was most likely hydrogen and that the stable intermediate was hydrochloric acid.

(ii) Although the addition of dry hydrogen chloride gas in the presence of air is without effect (series 6), the addition of small amounts of anhydrous hydrogen chloride, carefully degassed by several sublimations in vacuum, shows a marked acceleration (series 7), in spite of the fact that chlorine is liberated in both cases.

Using amounts of hydrogen chloride measured with a gas pipette, the effect of the concentration (series 8, curve *d*, 0·003 moles hydrogen chloride/mole N-chlorosuccinimide ; curve *e*, 0·009 mole hydrogen chloride/mole N-chlorosuccinimide) could be demonstrated ; the induction period was thus reduced below the value obtained by the pre-treatment and probably practically abolished.

All these results seem to support the following mechanism :

(1) A small quantity of hydrogen chloride is formed probably by the reactions :

$$\mathrm{SNCl} \rightleftharpoons \mathrm{SN}\cdot + \mathrm{Cl}\cdot \quad [\mathrm{SNCl} = \text{N-chlorosuccinimide}]$$
$$\mathrm{Cl}\cdot + \mathrm{H_3C{-}C_6H_5} \rightarrow \mathrm{ClH} + \cdot\mathrm{H_2C{-}C_6H_5}.$$

(2) It is known that :

$$\mathrm{ClH} + \mathrm{SNCl} \rightarrow \mathrm{Cl_2} + \mathrm{SNH}.$$

(This equation is not meant to represent the mechanism of a reaction step but merely the known facts.)

$$\mathrm{Cl_2} \rightleftharpoons 2\mathrm{Cl}\cdot$$

(3) Finally, the chlorine atoms favour a chain reaction by one or both of the following steps :

$$(a) \quad \mathrm{C_6H_5{-}CH_2}\cdot + \mathrm{Cl_2} \rightarrow \mathrm{C_6H_5CH_2Cl} + \mathrm{Cl}\cdot$$
$$(b) \quad \mathrm{C_6H_5{-}CH_2}\cdot + \mathrm{SNCl} \rightarrow \mathrm{C_6H_5CH_2Cl} + \mathrm{SN}\cdot$$

One is thus led to a degenerate branching-chain mechanism of the type described by Semenoff[6] ; such systems show long induction periods, followed by a reaction which may become explosive (bell-shaped rate curve).

It is known that reactions of this type are occasionally initiated with suddenness, and may sometimes result in accidents (see following letter). The effect of light would thus consist in the direct or indirect formation of chlorine atoms which, after having used up the oxygen, would initiate the branching chain. It appears, however, that several different phenomena remain to be elucidated before giving a concrete meaning to the 'mean chain-length' (quantum yield) which we have measured.

It would naturally be premature to generalize our results to all free-radical reactions of N-halogenimides. We do not believe, however, that we are dealing here with an exceptional case. Indeed, preliminary tests on the thermal reaction of N-bromosuccinimide on toluene show that this reaction is similar in nature (see, however, the experiments of Buu-Hoï[7] and Karrer[8] carried out in carbon tetrachloride solution). Furthermore, we observed in this case the transitory appearance of the coloration due to molecular bromine. This is obviously the reaction stage corresponding to step 2 in the above scheme.

We are following up the study of these thermal and photochemical reactions and hope to extend them, on one hand to true allylic systems, and on the other, to different sources of atomic halogens[9].

One of us (P. A. G.) desires to express his thanks to the Institute of Applied Scientific Research (I.R.S.I.A.), Brussels, for a fellowship, which has enabled him to do this work.

Dangers Attendant on the Use of N-Halogenimides in Organic Reactions

It is our duty, we believe, to direct the attention of research chemists to a tragic accident which should stand as a warning to all users of N-halogenimides. Our collaborator and friend, Dr. H. De Graef, who was a man of great experience and skill, was carrying out the chlorination of xylene by means of 1,3-dichloro-5,5-dimethylhydantoin, when a violent explosion occurred. Wounded and badly burned, De Graef survived only three days.

It is essential to remember that some of the reactions of N-halogenimides can be extremely violent even in the absence of peroxide. Several such reactions have been observed in this laboratory, namely :

N-chlorosuccinimide + benzylamine
N-chlorosuccinimide + aliphatic alcohols
3-nitro-N-bromophthalimide + tetrahydrofurfuryl alcohol.

Among cases reported in the literature the following may be mentioned here :

N-bromosuccinimide + hydrazine hydrate[1].
N-bromosuccinimide + diallyl sulphide[2].
N-bromosuccinimide + aniline[3].

In some cases we have noticed a vigorous evolution of chlorine or bromine in reactions carried out with 1,3-dichloro-5,5-dimethylhydantoin and 3-nitro-N-bromophthalimide respectively.

Peroxides must, of course, be handled with great care, and attention is directed, once more, to the danger of using chloroform, as recommended in the first edition of "Organic Syntheses"[4], for the recrystallization of benzoyl peroxide.

Every possible precaution should therefore be taken when using these reagents, and reactions of this type should be done on a small scale only.

A Colour Reaction distinguishing between Adrenaline and *nor*-Adrenaline on Paper Chromatograms

In recent studies we were concerned with the detection of traces of *nor*-adrenaline in preparations of adrenaline derived from natural sources. Colorimetric methods[1,2] proved to be of limited value with low concentrations of *nor*-adrenaline ; but excellent results were obtained with paper chromatography, using modifications of the methods described by James and others[3,4]. The adrenaline samples are dissolved in methanol containing a minimum quantity of hydrochloric acid, and then transferred to paper strips for descending chromatography, or to circular disks of filter paper for chromatography by Rutter's technique[5]. Water-saturated phenol is used as the developing solvent in an atmosphere of hydrochloric acid[4]. The paper chromatograms are then dried and sprayed with an appropriate colour reagent.

The commonly-used ferricyanide colour reagent[3] produces browns and pinks which are not very sharply defined, especially when microgram quantities of *nor*-adrenaline are being sought in the presence of milligram quantities of adrenaline. More satisfactory results can be obtained by spraying the chromatograms with a solution of 0·5 gm. sodium β-naphthoquinone-4-sulphonate dissolved in 100 ml. of 0·2 *M* borate buffer at *p*H 8·9, the reagent having a final *p*H of 8·6. The solution should be freshly prepared just before use. With this reagent *nor*-adrenaline develops an intense blue colour slowly over a period of 15–30 min. Adrenaline produces a pink colour, while dihydroxyphenylalanine gives a yellow colour which gradually changes to a blue-grey. This colour difference should be of value in distinguishing dihydroxyphenylalanine from *nor*-adrenaline, since their R_F values are quite close[1]. At lower *p*H values (8·3–7·5), the paper background becomes badly discoloured, although the *nor*-adrenaline colour develops more rapidly. Exposure of the paper chromatogram to ammonia may be necessary before spraying if excessive amounts of acid are present.

This colour reaction is highly sensitive, being capable of detecting less than one microgram of *nor*-adrenaline per square centimetre of paper.

Lamellar Compounds of Graphite with Chromyl Chloride and Chromyl Fluoride

The ability of graphite to form lamellar compounds by occluding certain other substances (fluorine, boron, oxygen, potassium, rubidium, caesium and ferric chloride) between its layer planes has been known for a considerable time. No new compounds of this type have, however, been reported for the past fifteen years, though attempts have been made to intercalate other volatile compounds in graphite. Thus Ruedorff and Schulz[1], who studied the ferric

'38 Dept.

chloride complex, were unable to prepare graphite complexes with either the triiodides or chlorides of arsenic, antimony and bismuth, and also failed to effect the intercalation of aluminium chloride. We have recently succeeded in preparing graphite complexes by the action of chromyl chloride and chromyl fluoride on graphite.

Qualitative tests showed that graphite swelled to almost twice its original size when warmed with its own volume of chromyl chloride. Even after thorough washing with carbon tetrachloride, in which chromyl chloride is readily soluble, a substance which analysis showed to be chromyl chloride could still be liberated from this treated graphite by heating the latter to between 200° and 300° C. This evolution was accompanied by exfoliation of the graphite and at least a hundred-fold increase in the volume of the latter.

The graphite used was a highly crystalline flake graphite from Uley, South Australia, purified by flotation and subsequent chemical treatment until its ash content had been reduced to less than 1 per cent. This material was screened into two fractions, the particle size being approximately 300 µ in one fraction and 40–80 µ in the other. Portions of each fraction were heated with four times their own weight of chromyl chloride at 100° C. for 24 hr., then washed with carbon tetrachloride and dried at 110° C. The products were analysed by first fuming with concentrated sulphuric acid, then ashing. The coarser sample was found to contain 43·0 per cent chromyl chloride and the finer 36·3 per cent. These large amounts are comparable with the amounts of ferric chloride held in the graphite – ferric chloride complex as found by Rüedorff and Schulz[1] and confirmed by Croft[2].

The exfoliation which accompanied the heating of these graphite – chromyl chloride complexes is typical of the lamellar compounds of graphite. Stability to solvents including aqueous acids and alkalis, which is a feature of the graphite – ferric chloride complex, is also shown by the new complex. Confirmation of the lamellar nature of this compound was obtained from X-ray diffraction measurements which showed that, as in the case of other graphite compounds, the carbon layer planes of the graphite are moved apart, in this instance from 3·45 A. to 9 A.

Following the intercalation of chromyl chloride, preparation of the corresponding fluorine compound was attempted with equal success. In this case it was found that graphite swelled immediately when placed in contact with chromyl fluoride at room temperature. Water-washed complexes obtained from this reaction exhibited an even greater degree of exfoliation than graphite – chromyl chloride when heated.

We wish to thank Mr. A. D. Wadsley for obtaining X-ray diffraction data for the graphite – chromyl chloride complex. A more detailed account of further studies on these complexes will be published elsewhere.

Course of the Oxidation of Olefins by Chromic Acid

A FURTHER study of the oxidation of olefins by chromium trioxide in acetic anhydride[1] has now shown that the initial phase consists of two distinct reactions: (*a*) attack at a methylene group adjacent to the double bond; (*b*) oxidation at the double bond. The last reaction has been observed with all the olefins yet examined; allylic substitution (*a*) occurs to an appreciable extent with some olefins, with others it cannot be recognized.

The evidence for (*a*) is derived chiefly from a study of the oxidation of tetramethyl ethylene (I) and octene-1 (IV). 2 : 3-Dimethyl but-2-en-1-al (II) has been identified in the products of the oxidation of (I) by chromium trioxide in acetic anhydride; acetone and the monoacetate of 2 : 3-dimethylbutan-2 : 3-diol (III) are also formed. It is difficult to imagine that (II) can arise in any way other than by the attack of the oxidizing agent on the methyl group. This conclusion is reinforced by the observation that (II) is also formed from (I) by oxidation with selenium dioxide. Further support is given by the isolation of oct-1-en-3-one from octene-1 (V) from the products of oxidation by chromium trioxide in acetic anhydride.

The interpretation of the course of the oxidation at the double bond is not entirely unambiguous from observations on these olefins, in that fission occurs to a considerable extent. Clear evidence of the nature of the initial phase of the oxidation of the double bond is afforded by an examination of the behaviour of camphene (VI) and of di*neo*pentyl ethylene (VII). From both these olefins the corresponding epoxide has been isolated and is the major product of the oxidation.

$\mathrm{Me_2C{:}CMe_2}$ I

$\mathrm{Me_2C{:}C(Me)CHO}$ II

$\mathrm{Me_2C(OAc).C(OH)Me_2}$ III

$\mathrm{CH_3(CH_2)_4.CH_2.CH{:}CH_2}$ IV

$\mathrm{CH_3(CH_2)_4.CO.CH{:}CH_2}$ V

The comparative stability of the epoxides from (VI) and (VII) no doubt permits of their survival during the reaction and the subsequent operations for isolating the products. Less resistant epoxides cannot survive, but it is possible in some cases to infer their participation in the oxidation; the presence of (III) in the products of the oxidation of tetramethyl ethylene finds a ready explanation on this basis.

$\mathrm{(CMe_3.CH_2)_2C{:}CH_2}$ VII

$\mathrm{(CMe_3.CH_2)_2CH.CO_2H}$ VIII

$\mathrm{CMe_3.CH_2.CMe{:}CH_2}$ IX

$\mathrm{CMe_3.CH_2.CHMe.CO_2H}$ X

$\mathrm{CMe_3.CH{:}CMe_2}$ XI

$\mathrm{CMe_3.CMe_2.CO_2H}$ XII

It is known that epoxides are also formed when some olefinic substances are oxidized in acetic acid by chromium trioxide[2–4], and it is a fair inference that the course of the reaction in acetic acid is the same as in acetic anhydride.

The extension of the idea of the initial formation of an epoxide to the oxidation by chromic acid in aqueous sulphuric acid has a serious difficulty; it is improbable that any epoxide is sufficiently stable to persist in aqueous sulphuric acid long enough to permit of its isolation. There are observations, however, which find a satisfactory explanation only if it is assumed that an epoxide is formed in the initial phase.

It is known that some olefins on oxidation by aqueous chromic acid in sulphuric acid give not only the expected fission products but also acids which contain the same number of carbon atoms as the original olefin. Thus, di*neo*pentyl ethylene (VII) gives a good yield of di*neo*pentyl acetic acid (VIII); 2 : 4 : 4-trimethyl pentene-1 (IX) gives the fission product *neo*pentyl methyl ketone as well as 2 : 4 : 4-trimethyl pentanoic acid (X); 2 : 4 : 4-trimethyl pentene-2 (XI) yields acetone and trimethyl acetic acid as well as 2 : 2 : 3 : 3-tetramethyl butanoic acid (XII). In all these examples it is known that the epoxide isomerizes to the aldehyde corresponding to the acid isolated; there is good qualitative agreement between the extent of this isomerization and the yield of the acid in the oxidation.

An alternative hypothesis based on the assumption that a glycol is the initial product of the oxidation is less satisfactory; the rate of oxidation of glycols is in general greater than their rate of isomerization.

We acknowledge substantial support from the Research Group of the Institute of Petroleum, assistance from the Research Fund of the University of London and a maintenance grant from the Department of Scientific and Industrial Research.

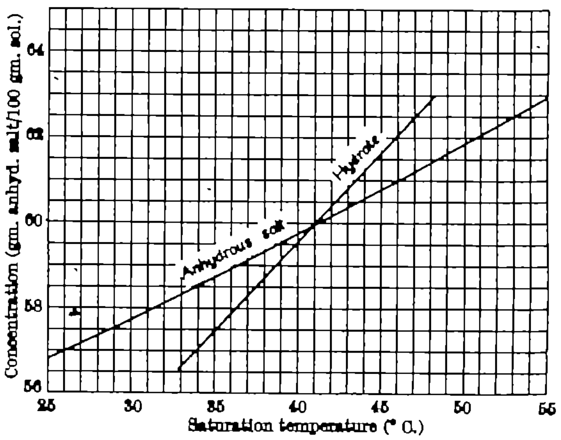
Solubility of Ethylenediamine D-Tartrate in Water

In a recent paper[1], A. C. Walker has given tables and curves for the solubility–temperature relationship in the system ethylenediamine D-tartrate (anhyd.)–ethylenediamine D-tartrate monohydrate–water. Dr. Walker shows that the salt decomposes slowly in solution, and the consequent change of composition of the solute during the time taken by the solubility determinations introduces some uncertainty in the results. Usually, when preparing a solubility curve, a considerable time must be allowed, at each observed temperature, for equilibrium between solution and solute to be attained. The change of composition of the solute during the experiments is probably responsible for the difference in level, of the order of 1° C., in two of the published curves.

In our work on growing large crystals of water-soluble substances, we have for some time been using a method for the direct estimation of the saturation temperature of solutions. The solution is circulated through a cell in which it is continuously brought into equilibrium with the solid phase being studied. Any departure from equilibrium in the cell is detected by observing a simple optical effect near the surface of a piece of crystal. The bulk of the solution is merely required to be uniform and free from solid; it is not necessary that it should at any stage be exactly at its saturation temperature.



We have used the procedure for obtaining the accompanying solubility curves of ethylenediamine D-tartrate and ethylenediamine D-tartrate hydrate. The solutions were prepared from the pure recrystallized anhydrous salt and distilled water only, so that the *p*H was approximately 6·0. The experimental conditions allowed about thirty points to be obtained in three hours for each curve. Decomposition of the solute in this period is slight, and we believe that our values are not in error by more than ± 0·1° C. It was found possible to follow the curves a considerable way into the regions where the solid phases studied are metastable only. To the extent to which they are shown in the graph, the curves are plotted from measured points and are not extrapolated.

It is intended to publish the method and results with more detail elsewhere.

Complement Fixing Antigen in *T*5 *coli* Bacteriophage

Complement fixation with animal viruses has long been known, and Hoyle[1] by the use of the complement fixation reaction has demonstrated a soluble influenza virus antigen which appears in infected cells of the chick embryo prior to the time in the growth-cycle at which infective virus can be found. Up to the present time, so far as I am aware, complement-fixing antibody to the bacterial viruses has not been demonstrated, nor has there been sought in phage-infected cells material analogous to the soluble influenza antigen of Hoyle. However, a conversation with Sir Macfarlane Burnet prompted a search for such substances.

A rabbit serum obtained by immunization with the *coli* phage *T* 5 contained a high titre of complement-fixing antibody. The complement-fixing activity of broth preparations of *T* 5 was related directly to their titre of infective phage, reduction of the phage titre by filtration resulting in a parallel reduction in antigen titre. The phage antigen–antibody system behaved ike other large-particle complement-fixing systems. No zones of optimal antigen or antibody titre were ound. Phage inactivated by heating at 73° C. or by precipitation with acid alcohol retained its antigenic activity. The antibody was specific for T5, little or no rossing occurring with other phages of the *T* series.

One-step growth-curves of T5 in *coli B* in glucose meal broth with $0\cdot001M$ calcium chloride showed a minimum latent period of 42 min. and completion of he cycle in 70 min., the average burst size varying rom 100 to 200 particles per cell. The content of phage antigen and infective phage in the cells during the latent period was studied by the cyanide lysis technique of Doermann[2]. Cells grown in broth with aeration to a concentration of approximately 5×10^8 per ml. were infected at the rate of two phage particles per cell. 10-ml. aliquots were withdrawn at various times and unadsorbed phage removed by centrifugaion. The unadsorbed phage content of the supernatant fluid was titrated, the fluid discarded and the nfected cells resuspended in 1 ml. of broth with $0\cdot02M$ sodium cyanide. This tenfold concentration of the cells was necessary to obtain amounts of phage which could be detected serologically. After lysis, the supernatants of the cyanide lysates were tested for infective phage and for antigen.

Nine minutes after infection, phage antigen but no nfective phage could be recovered from the cells. At 12–20 min. after infection neither infective phage nor phage antigen could be detected. At 24 min. large amounts of antigen were found but no infective phage. After 25 min., infective phage and phage antigen were both found; but the titre of antigen was considerably greater than could be accounted for on the basis of infectivity. Thereafter, up to the end of the latent period, both infective phage and phage antigen increased in amount; but the quantity of antigen recovered was always greater than could be accounted for by the amount of infective phage freed by cyanide lysis.

These results may be interpreted as further evidence in favour of the hypothesis of disintegration of the invading virus particle[3]. They also demonstrate that during the early part of the latent period, not only does the virus lose its infectivity, but also its antigenic character disappears. This situation continues until half the latent period has passed, and then material can be detected in the infected cell which is not yet the complete infective virus but which has the antigenic character of the virus. In the light of our present knowledge of phage synthesis, it is significant that it is also at this stage that the deposition of significant amounts of virus deoxyribonucleic acid takes place.

This demonstration of the presence in phage-infected cells of material that can be measured by serological methods should prove of value in studies of the processes involved in chemical inhibition of phage production, and in reactivation of phage inactivated by ultra-violet light and X-rays.

A full account of the work will be published elsewhere.

Effect of Antilymphocytic Serum on Suspensions of Lymphocytes *In vitro*

SERUM which has a powerful antilymphocytic effect *in vivo* can be prepared by immunizing an animal with injections of suspensions of heterologous lymphocytes[1,2]. The mechanism by which such a serum brings about a fall in the lymphocyte count when injected into an appropriate animal is uncertain, and it was felt that some light might be thrown on this question by studying the effect of the serum on suspensions of lymphocytes *in vitro*.

Antilymphocytic serum (rabbit-anti-rat) was prepared according to the method of Cruickshank[2], with one modification only, namely, that the immunizing injections were given subcutaneously instead of intraperitoneally. The serum was heated to 56° C. for 1 hr. to diminish anti-complementary activity. To test its efficacy, 2·0 ml. of the serum was injected intraperitoneally into a black-and-white hooded rat, total and differential leucocyte counts being made before and at intervals after the injection. A profound lymphopænia developed, the absolute lymphocyte count falling from 6,700 cells/c.mm. before, to 730 cells/c.mm. four hours after, the injection. On the other hand, no significant fall in lymphocyte count occurred in a rat which received an intraperitoneal injection of 2·0 ml. of normal rabbit serum.

For the *in vitro* test, suspensions of lymphocytes in Tyrode's solution were prepared from lymph nodes of black-and-white hooded rats, as described by Cruickshank. The cells were washed four times with Tyrode's solution and the final suspensions adjusted to a count of approximately 40,000 lymphocytes per c.mm. 0·4 ml. of suspension was placed in each of six glass ampoules (2·0 ml. capacity) and to these was added, respectively: 0·4 ml. antilymphocytic serum; 0·4 ml. antilymphocytic serum and 2 M.H.D. guinea pig complement; 0·04 ml. antilymphocytic serum, 0·36 ml. Tyrode's solution and 2 M.H.D. complement; 0·4 ml. normal rabbit serum; 0·4 ml. normal rabbit serum and 2 M.H.D. complement; and 0·04 ml. normal rabbit serum, 0·36 ml. Tyrode's solution and 2 M.H.D. complement. After samples had been removed for counting, the air in the ampoules was replaced by a mixture of 95 per cent oxygen and 5 per cent carbon dioxide and the ampoules were sealed. They were then attached to a mechanical mixer of the rotating drum type, which was placed inside the incubator (37° C.) and allowed to turn very slowly (10 r.p.m.). Further samples for counting were taken after 2 hr. and again after 18 hr. incubation.

The cell counts were made in a hæmacytometer after dilution with a solution of eosin in Tyrode's solution (1 in 2,000), as described by Schrek[3], the total count and the proportion of stained cells being recorded in each case. As the accompanying table indicates, none of the total counts showed any significant change following incubation. The proportion of stained cells—dead cells according to Schrek—increased slightly but to approximately the same extent in each case.

It thus appears that antilymphocytic serum has no effect on suspensions of lymphocytes *in vitro*. This suggests that the action of the serum *in vivo* is probably not due to direct destruction of lymphocytes in the blood stream.

Our observations are at variance with those of some other workers[4] who have reported agglutination

Type of serum	Final dilution of serum (per cent)	Whether complement added	Lymphocyte counts					
			Pre-incubation		After 2 hr. incubation		After 18 hr. incubation	
			Total count	Proportion of stained cells (per cent)	Total count	Proportion of stained cells (per cent)	Total count	Proportion of stained cells (per cent)
Normal	50	No	17,150	21	17,650	21	20,150	57
Normal	50 approx.	Yes	21,150	22	20,100	24	17,050	60
Normal	5 approx.	Yes	19,000	26	17,700	31	17,050	70
Antilymphocytic	50	No	14,850	36	13,100	41	15,000	71
Antilymphocytic	50 approx.	Yes	18,450	26	20,950	34	21,800	70
Antilymphocytic	5 approx.	Yes	21,750	35	18,900	26	18,550	54

of lymphocytes *in vitro* by antilymphocytic sera; but the tests they describe are difficult and notoriously liable to give falsely positive results. Admittedly, in our experiments continuous mixing of the suspensions occurred; but this was extremely gentle and not likely to have masked the effect of agglutinating antibodies had such been present.

It is of interest that Robertson[5] found that adrenal cortical extracts, which were markedly antilymphocytic *in vivo*, also had no apparent effect on lymphocytes *in vitro*. It is true that Robertson relied on counts of total number of cells only, and more recently Schrek[6] has claimed that some significant change in the proportion of stained cells does occur after incubation with cortical extracts; but the effect was very slight and would not seem to afford any explanation of the lymphopenia which this material produces *in vivo*.

Since antilymphocytic serum and cortical hormones both cause a marked lymphopenia on injection, but have little or no effect on lymphocytes *in vitro*, it might be suggested that the *in vivo* effect of the serum is mediated solely by an adrenal cortical mechanism. This, however, is not the case, since we have found[7] that the antilymphocytic effect of the serum, though possibly diminished, is still apparent in adrenalectomized animals.

This work was assisted by grants from the Medical Research Council, for which we wish to express our thanks.

Vitamin B_{12} Content of Soft- and Hard-shell Clams

MICROBIOLOGICAL assays for vitamin B_{12} content were made on soft-shell clams (*Mya arenaria*) and hard-shell clams or quahaugs (*Venus mercenaria*) from the waters off the coast of Massachusetts and Rhode Island. Assays were also made on commercially canned clams, both whole and minced, and on calf, beef, and pig livers obtained through normal retail outlets.

The samples, diluted 1 : 100 with distilled water, were disintegrated in a Waring blendor and extracted under benzene at 55° C. for 24 hr. More efficient extraction of vitamin B_{12} was thus obtained than by slurrying in a Waring blendor and immediately assaying[1]. One sample of soft-shell clams was lyophilized before being extracted; the material was frozen with a mixture of solid carbon dioxide and alcohol (− 78° C.) and dried at the resulting low temperature for 15 hr. *in vacuo* (pressure, 0·2 mm. mercury).

The assay tubes were prepared in the usual manner for microbiological assay. The basal medium employed was that of Winsten and Eigen[2], except that 0·5 gm. of vitamin C was added per litre of medium. *Lactobacillus leishmanii* 313 (*ATCC* 7830) was used as the test organism. Titrimetric evaluation of the response of the test organism was made with $N/10$ sodium hydroxide, bromthymol blue being used as an internal indicator. Duplicate tubes containing 10 ml. of assay solution were used at four levels of sample material, and the results for the series were averaged. Maximum response was obtained at 0·4 μgm. of vitamin B_{12}.

All the fresh samples of soft- and hard-shell clams had higher contents of vitamin B_{12} (6·0–9·7 μgm. per gm. of dry weight) than any of the animal livers assayed (1·3, 1·1 and 2·6 μgm. per gm. of dry weight, for pig, beef and calf liver, respectively). That clams are a richer source of this vitamin than animal livers may be of some importance in pernicious anæmia therapy.

Assays for dissected portions of soft-shell clams indicated that the visceral mass contained a higher concentration of vitamin B_{12} (16·3 μgm. per gm. of dry weight) than other parts of the clam assayed (2·0 μgm. for foot and siphon and 2·1 μgm. per gm. for the remainder).

The entire vitamin B_{12} content of the dissected soft-shell clams as calculated from weighted averages of the values for the dissected portions was confirmed within experimental error by the concurrent assay of an undissected duplicate.

The drained solids of the commercially canned whole clams contained only about half as much vitamin B_{12} on the dry basis (3·8 μgm. per gm.) as the fresh clams. It is uncertain whether some of the vitamin B_{12} activity of the canned material was lost during processing, or whether the lower vitamin content was due to a difference in species or locality of collection.

Canned minced clams assayed about 50 per cent lower in vitamin B_{12} content of drained solids than did canned whole clams. This lower vitamin content may possibly be explained by the fact that the visceral mass is removed from clams before they are minced for canning and, as already pointed out, there is a higher concentration of vitamin B_{12} in the clam's digestive tract. It now appears that this discarded material might be an excellent source of vitamin B_{12} for animal-feed supplements.

The lyophilizing process had no detrimental effect n the vitamin B_{12} potency of soft-shell clams. If clams are found useful for therapeutic purposes, this fact is of interest, because large amounts can be conveniently prepared for storage in this manner.

Use of a Sheep Abortion Virus as a Test Virus for Chemotherapy Work

A STRAIN of abortion virus, isolated by us from a local case of sheep abortion in March 1950 and apparently similar to the virus isolated by Stamp, McEwen, Watt and Nisbet[1], has been extensively used in an *in ovo* 'screening test'. It has proved so satisfactory for this purpose that it is felt its usefulness should be more generally known. The virus n infected membranes remains viable indefinitely at − 20° and for some weeks at 0°, and regularly produces well-defined lesions on the chorioallantoic membrane; in both these respects it is superior to many other large viruses. So far as is known, it is not pathogenic to man.

Drug	Inhibitory dose (mgm./egg)		* Activity in mice against Nigg virus (drug given subcutaneously from day of infection)
	Abortion	Nigg	
Chloromycetin	1·0	2·0	+ + (0·02 mgm./gm./day)
Aureomycin	0·25	0·25	+ + + (,,)
Terramycin	0·06	0·06	+ + + (,,)
Penicillin	Inact. 2,000 u.	2,000 u.	+ (4,000 u./mouse/day)
Sulphathiazole	Inact. 14·7	14·7	+ (0·2 mgm./gm./day)
p-Aminobenzoic acid	Inact. 27·4	Inact. 13·7	0 (2 mgm./gm./day, orally)

* + = prolongation of life only; + + = no deaths, but lungs involved; + + + = no deaths, lungs not involved.

Groups of 10-day chick embryos are used for the test. The drug, in 0·2 ml. diluent containing 1,000 u. penicillin and 1,000 u. streptomycin per ml., is introduced into the yolk sac; 0·2 ml. of a broth suspension of the virus is inoculated on to the chorioallantoic membrane within four hours. After a further seven days incubation, the membrane is removed and, since the lesions are very distinct, readily assessed.

To date 250 compounds have been tested, but only terramycin, aureomycin and chloromycetin have been found active.

It is probable that the abortion virus is related to the psittacosis group. To test this hypothesis an investigation into the effect of drugs on mouse pneumonitis (Nigg) virus was carried out under the same test conditions; results are given in the accompanying table. Both viruses are sensitive to terramycin, aureomycin and chloromycetin, but the abortion virus, unlike Nigg virus, is not attacked by penicillin or sulphathiazole; the implications of these results are being studied further. Full details of the work will be published elsewhere and evidence presented to justify the belief that this type of *in ovo* test will detect compounds likely to be of chemotherapeutic value. It requires smaller amounts of drug and provides indications similar to those yielded by the more laborious mouse tests (see table).

We wish to thank Sir Jack Drummond and Mr. C. E. Coulthard for their interest in this work, and Dr. A. D. McEwen for much information.

Is Age of Parents Important in Sheep?

A SITUATION provoking speculation has been found during the course of a preliminary investigation of one-shear ($1\frac{1}{2}$-year old) rams offered for sale at the Feilding Stud Ram Fair. Stock entered in the Fair, the most important of its kind in New Zealand, come from the Manawatu and neighbouring Wairarapa and Hawke's Bay districts and are purchased by breeders throughout New Zealand, Australia and South America. Data used in these analyses were derived from the catalogues of the 1948, 1949 and 1950 sales and the 1948 Flock Book of the New Zealand Romney Marsh Breed Society.

Of the 612 rams offered for sale in the three years, 52·6 per cent were sired either by lambs or by one-shear rams. The offspring of the one-shear rams brought the highest average price and had a lower rejection-rate than any other age. Similarly, an analysis of the 1948 Flock Book involving all Romney stud sheep in the Dominion shows that 49·5 per cent of the 1,580 rams single-entered (that is, to be used as stud sires) were sons of either ram lambs or untried one shear sires. However, Goot[1] has shown that one-shear sires comprise only 27·8 per cent of the sires available for use in those flocks static in numbers and consisting of 400 or more ewes.

Selection of rams for the Stud Fair and for single-entry in the Flock Book is almost solely on phenotype and certainly without reference to age of the parents, nor does this latter point interest buyers. Because of this, it would be expected that the sires of rams chosen for single-entry and for sale would be represented in the same proportion as they are used in the flocks. In this case only 27·8 per cent of the rams single-entered or offered for sale would be the sons of one-shear rams. However, the results show that they produce almost twice this number.

An analysis of the influence of age of dam shows that progeny of the youngest ewes achieve the highest average price, though the proportion of these is not greatly different from that expected from the age composition of dams[1].

For every sire recorded in the sale catalogues there are on an average a little less than two sons offered for sale.

Further analyses are planned to throw more light on these rather perplexing problems.

Biochemistry in the Taxonomy of Lichens

The application of biochemical methods to plant taxonomy was first made in the lichens, in 1867, when potassium hydroxide and calcium hypochlorite were found to give characteristic colour reactions when applied to the thallus of certain species. Most present-day lichenologists employ these reactions as an important character in the description of species. In a large number of lichen species the exact constitution of the lichen acids causing colour reactions is known, mainly owing to the researches of Zopf[1] and Asahina[2,3]. The latter has originated a method of microchemical analysis whereby the lichen acids can be determined by the form of the crystals which they produce under the microscope when recrystallized from various solutions[4], this method requiring the extraction of only a small portion of the thallus with acetone.

Use has been made of biochemical methods as an aid to taxonomy also in the flowering plants, and it has been found that many of the larger groupings, such as families, sections and genera, originally delimited on a purely morphological basis, are characterized also by biochemical differences[5]. The application of chemical methods in Phanerogams, however, has not yet reached the point at which species are distinguished on chemical characters. Penfold, Morrison and Smith-White, for example, class individuals of the Australian tree *Leptospermum citratum* containing different essential oils as "variety A" and "variety B" respectively[6]. In lichens, the tendency has been to regard chemically distinct individuals as distinct species, irrespective of whether morphological differences are present or not. This view, if carried to its logical conclusion, means that in many cases related species could be determined only by chemical analysis. This state of affairs has already been reached in certain lichen genera, for example, *Cladonia*. In the lichens the matter is further complicated by the fact that they are not simple organisms, but a fungus–alga consortium, and in most cases it is not known with certainty to what extent the formation of the characteristic lichen acids depends on the symbiotic union. In a few cases the fungal component has proved capable of producing the characteristic substance in pure culture without Algæ[7]. It is not unlikely that the same lichen fungus may produce distinct acids in symbiosis with different Algæ. The differentiation of 'chemical species' in the lichens therefore rests on a doubly insecure foundation.

The problem has already become acute in the taxonomy of lichens to the extent of forming a serious obstacle to the work of classification; for example, in one genus now under monographic study, it would be necessary to describe more than forty 'new species' on chemical grounds alone, without supporting morphological characters, if the present conventional treatment were adhered to. The increasing interest shown by taxonomists in other plant groups in the use of biochemical methods makes it necessary, if possible, to forestall difficulties of a similar nature which will undoubtedly arise as further use is made of biochemical criteria applied to taxonomy.

It is now suggested that morphologically indistinguishable individuals of plants (other than bacteria) which differ in their chemical characters should be included in the same species as distinct 'chemical strains', the nature of the compound present being indicated in brackets, together with quotation of tl taxonomic epithet previously used (if any) to desi nate the strain in question. The following are son examples of the treatment applied to lichen specie

Stereocaulon tomentosum Fr., Ch. str. I (stictic acid or typical strain).
" " " Ch. str. II (lobaric acid or 'sasakii'-stra (previously described as a distin species, *St. Sasakii*)
Cladonia chlorophaea (Flk.) Spreng., Ch. str. I (fumarprotocetraric ac or typical strain).
" " " " Ch. str. II (grayaninic acid 'grayi'-strain).
" " " " Ch. str III (cryptochlorophaeic ac or 'cryptochlorophaea'-strain).
" " " " Ch. str. IV (merochlorophaeic ac or 'merochlorophaea'-strain).
" " " " Ch. str. V (novochlorophaeic ac strain).
" " " " Ch. str. VI (usnic acid strain).

The strains containing grayaninic, cryptochlor phæic and merochlorophæic acids had been pr viously designated as distinct species with tl names *grayi*, *cryptochlorophæa* and *merochloropl.æ* respectively.

The application of this method registers the chen ical differences while keeping them outside the fram work of formal taxonomy, and thus avoids burdenir the latter with a mass of unnecessary epithets. I also enables the field-worker to determine his speci on a morphological basis. Continued attention shoul however, be paid to the constitution and distributio of the distinct chemical strains, for they have bee found, at any rate in some of the lichens, to b significant for distribution, occurring in separate part of the species' geographical area.

Permanent Preparations of Fungi Growing on Agar

The methods to be described here have been use in making preparations of predacious fungi from aga cultures, where it is important that hyphæ shoul be retained *in situ*; but they also appear to b generally applicable.

For making rapid preparations from living mater ial, a modification of the chlorazol black metho of Armitage[1] has been found satisfactory. Fron material growing in culture, agar blocks about 4 mm square are cut out with a scalpel, and the surface o the agar bearing the fungus is carefully sliced of with a razor blade to a uniform thickness of abou 200 µ. The treatment is then as follows: fix i absolute alcohol, 1 min.; stain in a saturated methy alcohol solution of chlorazol black E, 1 sec.; de hydrate in absolute alcohol, 10 min.; mount i 'Euparal' in a cavity slide, and harden by gentl heat.

This method is excellent for mycelium and thick-walled spores; but large thin-walled spores are apt to collapse as a result of the rather drastic treatment. As Armitage[1] points out, the chlorazol black stains more brilliantly if methyl alcohol is used as solvent rather than ethyl alcohol.

The thickness of the agar included in the preparation is sometimes a source of trouble in critical observation with high-aperture objectives. To avoid this, the following technique may be used which, though slower, gives beautiful preparations. Blocks of agar bearing the fungus, about 4 mm. square, are cut out and fixed in the following mixture: commercial formalin, 10 ml.; glacial acetic acid, 5 ml.; distilled water, 85 ml. For this formula we are indebted to Dr. B. Barnes. Material is fixed for at least 24 hr., but may be left in the fixative indefinitely without harm. The agar block is washed until it no longer smells of acetic acid, and then stuck, fungus downwards, on a No. 1 cover slip by means of Szombathy's gelatine, as recommended by Chamberlain[2]. The agar is allowed to dry in a warm place (not above 35° C.) until it begins to shrink; the surface bearing the fungus is prevented from shrinking by adhesion to the glass. When the agar is firmly attached to the cover slip, the block is sliced away with a sharp razor blade as close to the glass as possible. The material, still on the glass, is then stained with Heidenhain's hæmatoxylin, dehydrated by passage through a gradually ascending series of alcohols, cleared with terpineol and mounted in canada balsam. If desired, clearing may be omitted and 'Euparal' used as a mountant following absolute alcohol.

In this technique, any suitable stain may be used, but once alcohol has been applied to the preparation it is inadvisable to return to water, as swelling of the agar may cause it to become detached from the glass.

Details of these and other techniques will be given elsewhere.

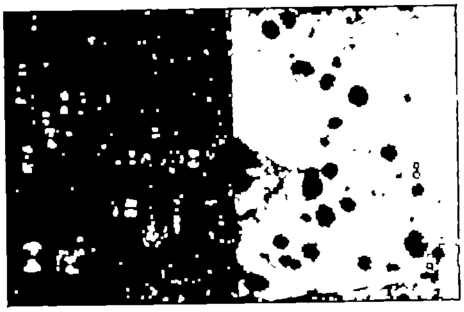
Corpora amylacea in the Central Nervous System

It has long been known that small round corpuscles may be found around the blood vessels of the central nervous system in subjects of advanced age. As the staining properties of these bodies are similar to those of starch, Virchow called them corpora amylacea. Several authors have examined them in attempts to determine their origin, but without definite result. The present contribution describes an attempt to define the morphology and some of the chemical properties of corpora amylacea, using the polarizing microscope as well as the periodic acid – leucofuchsin method[1].

Under the polarizing microscope, the round bodies show pronounced double refraction with a positive Maltese cross (Fig. 1), the path-difference being 15–20 μ in our sections. This finding does not agree with those previously given in the literature[2]. The character of the double refraction does not change in the imbibition test, suggesting that self-birefringent lipids may be considered as the principal constituents of these bodies.



Sections of corpora amylacea: (1) polarized light, crossed nicols and Senarmont compensation (× 80); (2) periodic acid – leucofuchsin method (× 80)

The myelin sheath gives a positive aldehydic reaction after treatment with periodic acid; the round bodies were treated similarly in order to obtain information about the possibility of a genetical relationship between them and the myelin sheath. Frozen or paraffin-embedded sections of corpora amylacea showed a brilliant rose-purple colour (Fig. 2); myelin sheath, however, gave a positive result only in frozen sections. In the case of corpora amylacea, the reaction was not inhibited if the bodies were extracted with solvents which would remove cerebrosides. This is probably due to the fact that the cerebrosides which are responsible for the aldehyde reaction are linked to proteins, thereby becoming unextractable[3].

Summarizing the above results, it is suggested that the principal constituents of corpora amylacea are lipids, and that their intense aldehydic reaction after treatment with periodic acid indicates that they possibly belong to the carbohydrate-containing cerebrosides. It well may be that the origin of corpora amylacea is in the cerebrosides of the degenerated myelin sheath.

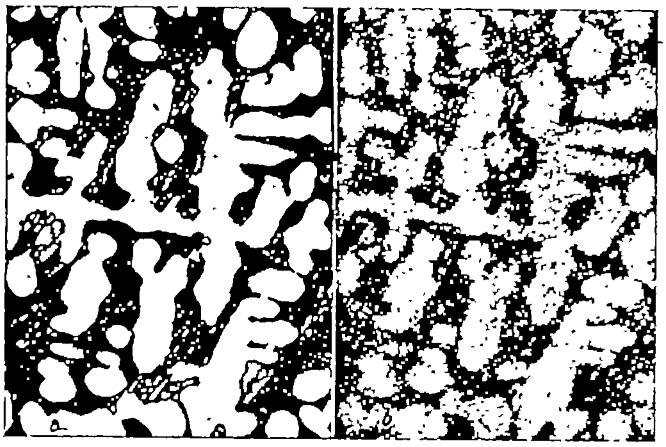
Nuclear Reaction Radiography

Autoradiography has been employed for many years for the purpose of determining the distribution of an element in a given material. The essential requirement for the use of this method is that the element in question itself should emit a radiation which can be registered, on a photographic film pressed against the surface of the sample. To make an element betray its presence in this way, one provides a certain fraction of marked atoms by adding a small amount of radioactive isotopes of the same element.



(*a*) Photomicrograph of the metal surface. Light areas: iron; darker parts: eutectic of iron and Fe_2B. × 100

(*b*) Reaction radiograph of the same surface as that shown in (*a*). Dark spots are produced by α-particles, showing position of reacting atoms of boron. × 100

I have investigated another method, which may be termed nuclear reaction radiography, since it makes use of the property of the non-radioactive element in question of reacting with an external particle radiation in such a way that a new radiation is born in the process, which is then registered on the photographic film. To use this method, the photographic film must be insensitive to the primary particle radiation used for exciting the reaction. This requirement would seem to restrict the species of available primary radiations at present to one kind, namely, neutrons. Another requirement is that the element to be detected should have a much higher probability of reacting with the primary radiation than other elements present in the material under investigation. This can be achieved in some cases by the choice of neutrons with suitable energy, making use of the fact that different reactions have different resonance energies. Finally, the radiation produced in the reaction must be of such a nature that it can be properly registered on the film.

Boron is one of those elements where the ordinary autoradiographic method fails, since no suitable radioisotope is available. Instead, conditions would seem to be favourable for the use of nuclear reaction radiography in this case. The reaction which suggests itself is:

$${}_5^{10}B + {}_0^{1}n \rightarrow {}_3^{7}Li + {}_2^{4}\alpha.$$

For thermal energy neutrons, the cross-section has the very high value of 3,000 barns. The α-particle is emitted with an energy of 1·5 MeV., which is a very favourable value for photographic trace production. The range of these particles is about 5 μ in the emulsion, and in iron it is considerably less than this. Hence, the method should be capable of yielding very high resolution. I have investigated this method, using Kodak Autoradiographic plates. These photographic plates should give very good resolution because (i) the emulsion is very fine grained, (ii) the emulsion can be stripped from the glass plate and mounted directly on the sample under investigation. A further advantage with this material is that the sensitivity to γ-radiation is very small, whereas the sensitivity to α-radiation is high.

The method has been tested on an experimental alloy made up of 98 per cent iron and 2 per cent boron. A small sample of this was ground polished and etched, and given a thin protective coating of collodion in order to keep the surface free from tarnish in the subsequent work (otherwise it will rust very readily). The collodion film was less than 1 μ thick. The freshly stripped, wet emulsion was placed on top of this and was allowed to dry in position, which made it adhere firmly to the sample. The sample was then placed in a light-tight container, where it was irradiated for 16 min. with neutrons from a cyclotron. A block of lead, inserted between the sample and the cyclotron, served to reduce as much as possible the amount of γ-radiation reaching the emulsion. The sample was surrounded by paraffin wax in order to obtain a favourable proportion of thermal neutrons. After irradiation, the emulsion was developed and compared with the metal surface in an ordinary microscope. The results are illustrated by the accompanying reproductions. It is evident that the emulsion stripped from the sample reproduces the distribution of boron quite accurately, and that it is possible to work at quite considerable magnification.

I am grateful to the Nobel Institute for Physics in Stockholm, where Mr. S. Thulin kindly carried out the cyclotron irradiation, and to Mr. L. Erwall of the Division of Physical Chemistry at the Royal Institute of Technology, Stockholm, who placed the Kodak Autoradiographic plate material at my disposal; this emulsion undoubtedly played an important part in the success of this experiment.

The Point-Charge in the Non-symmetric Field Theory

GAGANBIHARI BANDYOPADHYAY'S remark[1] about one of the spherically symmetric static solutions, that were given in a paper by one of us[2], is interesting, but it has not the meaning this author attributes to it. This solution cannot possibly refer to an electric charge at the centre, but only—if to anything electromagnetic—to a magnetic charge, that is, to an isolated magnetic pole. Indeed, the one component to which the six-vector is reduced in this solution is radial and is labelled by the indices 1 (referring to the radial direction) and 4 (referring to time). Now, in contrast to the conventional labelling, the present theory has to identify the electric field with the three components of the six-vector that do *not* include the index 4 (*if* the skew part of g_{ik} is to represent electromagnetism). The reason is that the theory definitely yields one and only one set of four Maxwellian vacuum equations. This set has to enunciate the vanishing of the *magnetic* four-current, not of the electric one; and this imperatively demands the association of labels indicated above. We may add that the necessity to reverse the convention is very satisfactory and is, in itself, likely to strengthen our confidence in the new theory. Indeed, very good reasons for reversing the conventional association were pointed out by Einstein[3] long ago and repeated by one of us[4] since.

Thus Bandyopadhyay's remark[1] really means that an isolated magnetic pole, attached to a finite mass, impossible according to the more stringent version, roposed by Einstein lately[5], of the non-symmetric heory. We might strengthen this argument by aying that, to introduce as a singularity what the eld equations definitely disallow where they hold, as a daring enterprise anyhow, justified only by he endeavour to investigate, at the then undeveloped tage of the theory, *all* spherically symmetric solutions.

But what about the electrically charged masspoint ? The same paper[2] (§§ 8 and 9) fully discusses his case as well, though it is analytically far more ntricate and has only recently found its explicit xpression (see Wyman[6]). It is gratifying to find that he only reasonable solution with a radial *electric* ield is not only *compatible* with Einstein's recent more stringent version, but, of necessity, complies ith it (see equations 30*b* and 23, *l.c.*[2]).

To sum up: the new theory exhibits a pleasing ack of symmetry with regard to electric and magnetic quantities. Even in its most stringent form it dmits of electrically charged mass-points, while solated magnetic poles are well-nigh inadmissible in ny form of the theory.

Effect of Cross-wind on a Projectile

THE usual formula for drift of a projectile due to ross-wind is:

$$z = w\,(t - x/v)\ \text{(ft.)}, \tag{1}$$

here w is velocity of cross-wind (ft./sec.), t is time f flight (sec.), x is range through air (ft.), v is muzzle elocity relative to the air (ft./sec.). At short times f flight it is not always easy to calculate $(t - x/v)$ ith reasonable speed and accuracy.

By integrating the equation of motion along the rajectory

$$mx = -\rho\,(v^2 + w^2)\,r^2 f_R, \tag{2}$$

here m is mass of projectile (lb.), x is range along he trajectory (ft.), ρ is air density (lb./ft.^{3}), r is adius of projectile (ft.), f_R is drag coefficient, and , w are as in (1), expanding in series and substituting n (1), we obtain

$$z = 0{\cdot}000067\ wvt^3\,d^2 f_R/m\ \text{(ft.)}. \tag{3}$$

Equation (3) is easy to use, but is valid at short times of flight only. The result is better at subsonic velocities than at supersonic velocities.

It is hoped that a full account of this will appear elsewhere.

This note is published by permission of the Chief Scientist, Ministry of Supply.

Negative Point-to-Plane Corona—a New Mode of the Discharge

A NUMBER of investigators[1,2] in the field of negative point-to-plane corona have reported on the unsteady nature of the discharge at high values of gap voltages. Reference has been made to the movement of the active spot about the point, and the formation of 'plural spots'. I have found that, with certain gap geometries, a new mode of discharge can be observed.

As the applied voltage is increased, the point discharge passes through an unstable 'switching phase', sometimes with two or more active spots, but quickly settles down to the new mode. This consists of a ring-shaped discharge fitting neatly and symmetrically about the point, almost like a halo. Its structure is similar in appearance to that of the single spot, namely, a miniature glow discharge, with a negative glow of pronounced luminosity, a Faraday dark space, followed by a diffused and flared positive column. As yet I have been unable to achieve sufficient optical resolution to observe the Crookes's dark space.

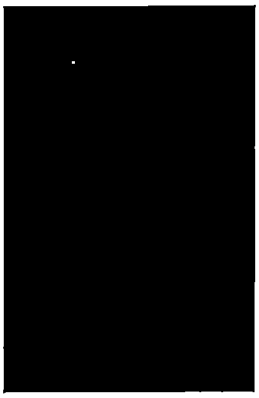

Fig. 1

It is obviously impossible to obtain a direct view on to the tip of the point, the line of vision being obscured by the plane; however, by using a highly polished plane, the image of the point and the discharge, in the plane, may be readily seen with the aid of a suitable optical system. Observations are best carried out in total darkness with a dark-adapted eye.

Fig. 1 shows a photograph of the ring on a 1-mm. diam. steel point, taken in this way; the point-to-plane gap was 10 mm., and the applied voltage and mean current were 10·9 kV., and 65 μamp., respectively. Fig. 2 shows a sketch of the point, drawn to the scale of Fig. 1, for the purpose of comparison.

In its new mode, the pulsating character of the corona persists, but oscillographic measurements

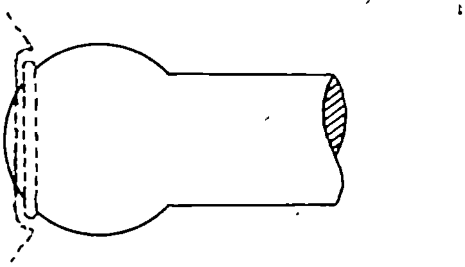

Fig. 2

indicate an apparent discontinuity in the frequency characteristic. A change in the mean current/gap voltage relationship, resulting in an increase in the charge per burst, is also evident.

A likely explanation of the phenomenon, which has so far gained considerable experimental support, is to be found in an extension of Loeb's[3] theory on the mechanism of Trichel pulses; that is to say, the new mode is engendered by space-charge considerations, as distinct from changes in Townsend's second coefficient, γ, for example.

A fuller report and discussion on the subject will be published in the near future.

A Relationship between Heat Conductivity and Viscosity of Liquids

ANDRADE[1] developed a theory of viscosity of liquids based on a model in which the molecules are regarded as executing vibrations essentially similar to those characteristic of the solid state, the chief difference between the solid and the liquid states being that in the latter the amplitudes of the vibrations are so large that molecules make collisions (resulting in 'temporary unions') with neighbours at every extreme displacement. His viscosity equation is

$$\eta = \frac{4}{3} \cdot \frac{m\nu}{\sigma}, \qquad (1)$$

where η is the viscosity of the liquid, m the mass of a molecule in the liquid, ν its vibration frequency, and σ the average distance between the centres of the molecules.

From an essentially similar model, Osida[2] deduced that

$$K = \frac{4k\nu}{\sigma}, \qquad (2)$$

where K is the heat conductivity of the liquid and k the gas constant per molecule.

From (1) and (2),

$$mK/\eta = 3k.$$

Multiplying each side by the Avogadro number N,

$$NmK/\eta = 3Nk,$$

or as the molecular weight $M = Nm$ and the molar gas constant $R = Nk$,

$$MK/\eta = 3R. \qquad (3)$$

Since R in calories is very nearly 2,

$$MK/\eta = 6;$$

K is in calories, and η in poises.

In the accompanying table are shown values for the molecular weight in the vapour state M, the heat conductivity at the boiling point (a 'corresponding' temperature) K_{bp} in calories, the viscosity at the boiling point η_{bp} in poises and MK_{bp}/η_{bp} of some 'normal' liquids, K for which is known fairly accurately from Bridgman's measurements[3]. Values for K_{bp} have been calculated from Bridgman's data at 30° and 75° C., assuming a linear relationship between K and temperature[4]. Values for η_{bp} are after Macleod[5]. It will be seen from the last column of the table that

Liquid	M	K_{bp}	η_{bp}	MK_{bp}/η_{bp}
Acetone	58·1	0 000414	0·00232	10·4
n-Pentane	72·1	320	200	11·5
Ether	74·1	328	205	11·9
Carbon disulphide	76·1	375	308	9·26
Toluene	92·1	319	248	11·9
Ethyl bromide	109	284	329	9·41
Ethyl iodide	156	261	371	11

$$MK_{bp}/\eta_{bp} = \text{constant}. \qquad (4$$

The mean value of the constant is 10·8. It is eviden from this that, to be applicable at the boiling point the numerical coefficient in equation (3) require modification. This can be done, satisfactorily enough only on examination of a number of liquids. Unfortunately, however, data on K are scarce. Further different methods of measurement yield varyin values. Until these difficulties are overcome, th numerical coefficient in equation (3) can be modifie tentatively to 5·4.

Elastic Constants of Galena

RECENTLY, Ramachandran and Wooster[1] hav obtained the elastic constants of galena, among other substances, from measurements on diffus reflexion of X-rays, and reported disagreement wit the values given earlier by one of us[2]. Ramachandran has also directed our attention to this in privat communications. This substance, in the light o such values, also figures as an exception in a pape by Lonsdale[3] dealing with the vibration amplitudes of atoms in cubic crystals. Its elastic constant have therefore been re-determined, employing th wedge method and a very much better crystal tha was available at the time of the earlier investigations. Frequencies in the range 2–12 Mc./sec., and (001) and (111) sections of different thicknesses ranging from 1·450 mm. to 1·929 mm., have been used. Constants now obtained along with the bulk modulus K in units of 10^{11} dynes cm.$^{-2}$ are $c_{11} = 12·70$, $c_{12} = 2·98$, $c_{44} = 2·48$ and $K = 6·22$. They show that the Cauchy relation is fairly well satisfied. c_{44} and c_{12} do not differ very much from those o Ramachandran and Wooster, whereas c_{11} is somewhat larger. These values are to be regarded a much more reliable than any published earlier.

FORTHCOMING EVENTS

Tuesday, July 10—Friday, July 13

MEDICAL RESEARCH COUNCIL OF IRELAND (at University College and Trinity College, Dublin).—Colloquium on "The Chemotherapy of Tuberculosis".

Thursday, July 12

UNIVERSITY OF LONDON (in the Physiology Theatre, St. Mary's Hospital Medical School, Paddington, London, W 2), at 5 p.m.—Prof F. Verzar (Basle): "One or Several Adrenal Cortical Hormones".

Friday, July 13—Sunday, July 15

BRITISH MYCOLOGICAL SOCIETY (at Bristol).—Plant Pathology Field Day, Bristol Meeting, and Cotswold Foray.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

CHEMIST for work on the co-ordination of research and development on insecticides and fungicides—The Secretary, Agricultural Research Council, Cunard Building, 15 Regent Street, London, S.W.1 (July 14).

DAIRY CATTLE HUSBANDRY OFFICER—The Director, Animal Breeding and Genetics Research Organization, Glenbourne, South Oswald Road, Edinburgh 9 (July 14)

LECTURER IN AGRICULTURAL SCIENCES at the Cheshire School of Agriculture, Reaseheath, Nantwich—The Director of Education, County Education Offices, City Road, Chester (July 14).

LECTURER IN MATHEMATICS—The Registrar, Technical College, Sunderland (July 14).

LECTURER IN METALLURGY at the Technical College of Monmouthshire—The Director of Education, County Hall, Newport, Mon. (July 14).

LECTURER IN PHYSICS, to teach Physics to B.Sc. (General) degree standard—The Principal, Enfield Technical College, Queensway, Enfield, Middx. (July 14).

RESEARCH DEMONSTRATOR IN BOTANY—The Secretary and Registrar, University College of North Wales, Bangor (July 14).

SCIENTIFIC OFFICERS (2, with good honours degree in botany or agricultural botany) for vacancies, one in grass breeding and one in grassland agronomy, at the Welsh Plant Breeding Station—The Registrar, University College of Wales, Aberystwyth (July 14)

SENIOR ASSISTANT ENGINEER—The Engineer to the Essex Rivers Catchment Board, Essex Rivers House, Springfield Road, Chelmsford, Essex (July 14).

CURATOR (University degree essential and the Museums Association Diploma desirable) IN ARCHAEOLOGY AND ANTHROPOLOGY—The Director, City Museum, Bristol (July 15)

DEMONSTRATORS IN THE BIOLOGY DEPARTMENT—The Registrar, University College of North Staffordshire, Keele, Staffs, endorsed 'Biology Demonstrator' (July 15).

LECTURER IN MATHEMATICS, and a LECTURER IN ANATOMY, at University College, Dundee—The Secretary, The University, St. Andrews (July 15)

READER or SENIOR LECTURER IN CHEMICAL PATHOLOGY, and a DEMONSTRATOR IN PATHOLOGY—The Registrars, The University, Manchester 13 (July 15).

SENIOR LECTURER, and a LECTURER, IN ENGINEERING—The Registrars, The University, Manchester 13 (July 15).

SENIOR PROFESSIONAL OFFICER (with an honours degree in agriculture, or some equivalent qualification, and specialized in field crops and in soil physics and chemistry), at the Sabi Valley Experimental Station, Division of Agriculture and Lands, Southern Rhodesia—The Secretary, Office of the High Commissioner for Southern Rhodesia, 429 Strand, London, W.C.2 (July 15).

DEPUTY CHIEF ENGINEER—The Chief Engineer, Southend Waterworks Company, 13 Cambridge Road, Southend-on-Sea (July 16).

DIRECTOR OF FISHERIES, East Bengal—The High Commissioner for Pakistan, 35 Lowndes Square, London, S.W.1 (July 16).

LECTURER IN THE ELECTRICAL ENGINEERING DEPARTMENT (industrial or analogous experience desirable, with special interests and experience in radio engineering with particular reference to microwave technique)—The Head of the Electrical Engineering Department, City and Guilds College, Exhibition Road, London, S.W.7 (July 16).

RESEARCH ASSISTANT FOR ELECTRON MICROSCOPY—The Registrar, The University, Leeds 2 (July 16).

VIROLOGIST (male) to undertake research on virus diseases of fruit and hops (with special reference initially to the latter crop)—The Secretary, East Malling Research Station, Maidstone, Kent (July 16).

READERSHIP IN MINING—The Assistant Registrar, King's College, 3 St. Thomas' Street, Newcastle-upon-Tyne (July 17).

ASSISTANT DIRECTOR (Technical Underground) IN THE CENTRAL RESEARCH ESTABLISHMENT, Stoke Orchard, Cheltenham—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/349 (July 18).

PRINCIPAL SCIENTIFIC OFFICERS and SENIOR SCIENTIFIC OFFICERS in the Ministry of Food: (a) in London, PRINCIPAL SCIENTIFIC OFFICER (with a degree in biochemistry with biological subsidiary subjects, and experience in quality control and manufacture of foods essential) to take charge of the section dealing with the technological aspects of food hygiene and welfare foods; (b) in Aberdeen, PRINCIPAL SCIENTIFIC OFFICER (with a degree in botany or biochemistry, research experience in plant physiology and plant biochemistry; industrial experience of processing of vegetable products essential) to take charge of the section dealing with vegetable dehydration; (c) in London, PRINCIPAL SCIENTIFIC OFFICER (with a degree in chemistry or biological sciences, and practical experience of research and development in food production) to maintain liaison between the Department's Scientific Adviser, other Government departments and branches of industry concerned with manufacture and use of foods for emergency purposes; (d) in London, SENIOR SCIENTIFIC OFFICER (with a degree or an equivalent qualification, including chemistry and biological sciences) to undertake investigations in quality and reduction of wastage in foods; (e) in London, SENIOR SCIENTIFIC OFFICER (with a degree in biochemistry, physiology or chemistry) for advisory and survey work in nutrition; a knowledge of modern theory and practice of nutrition is essential; (f) in Aberdeen, SENIOR SCIENTIFIC OFFICER (with a degree in biochemistry or botany; research experience in plant biochemistry desirable) to undertake research on biochemical problems—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting No. S.4037/51 (July 19).

SENIOR PRINCIPAL PRODUCTION ENGINEER, Admiralty Production Pool—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting No. S 4038/51 (July 19).

PROFESSIONALLY QUALIFIED CHEMIST as Assistant Secretary (Scientific)—The Secretary, Royal Institute of Chemistry, 30 Russell Square, London, W.C.1, marked 'Private' (July 20).

ASSISTANT LECTURER IN BOTANY, for B.Sc. (Agric.) and B.Sc. (Hort.) degree courses—The Registrar, Wye College, Wye, Kent (July 21).

BOTANIST (with a good honours degree, and research or other experience in plant breeding, genetics or horticulture) for fruit-breeding—The Secretary, East Malling Research Station, Maidstone, Kent (July 21).

CHEMISTS (Senior Scientific Officer, Scientific Officer, Senior Experimental Officer, Experimental Officer, and Assistant Experimental Officer grades) at the Ministry of Supply Radiochemical Centre, Amersham, to be concerned with the synthesis of compounds labelled with radioactive isotopes, particularly Carbon-14, and with allied research problems—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.365/51A (July 21).

EDUCATIONAL PSYCHOLOGIST (woman, with honours or research degree in psychology) in the Somerset Child Guidance Service—The Chief Education Officer, County Education Office, Trull Road, Taunton (July 21).

LECTURER IN PHYSICS, and a LECTURER IN PHARMACOLOGY—The Secretary, Royal Veterinary College and Hospital, Royal College Street, London, N.W.1 (July 21).

RESEARCH DEMONSTRATOR IN ZOOLOGY—The Registrar, The University, Sheffield (July 21).

RESEARCH OFFICER (Veterinary Physiologist) IN THE DIVISION OF ANIMAL HEALTH AND PRODUCTION, at McMaster Animal Health Laboratory, Sydney, N.S.W., to undertake research on animal physiology, especially on the physiology of the alimentary canal of ruminants—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 3445 (July 21).

ASSISTANT LECTURER IN THE HYDRAULICS DIVISION of the Civil Engineering Department—The Head of the Department of Civil Engineering, Imperial College of Science and Technology, South Kensington, London, S W.7 (July 23).

RESEARCH FELLOWSHIP IN THE DEPARTMENT OF MATHEMATICAL PHYSICS—The Deputy Secretary, The University, Birmingham 3 (July 25).

PRINCIPAL SCIENTIFIC OFFICER (with a first- or second-class honours degree, preferably in engineering, and some industrial and research experience) in the Mechanical Engineering Research Organization (Department of Scientific and Industrial Research)—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4041/51 (July 26).

LECTURER IN ENGINEERING—The Secretary, The University, Aberdeen (July 27).

ASSISTANT EXPERIMENTAL OFFICER or EXPERIMENTAL OFFICER IN THE HYDRAULICS RESEARCH ORGANIZATION (Department of Scientific and Industrial Research), Wallingford, Berks, to assist in hydrographic surveying of beaches and estuaries and also to assist in research into the effect of waves and currents on beaches—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting E.270/51 (July 28).

ASSISTANT LECTURERS IN ELECTRICAL ENGINEERING—The Registrars, The University, Manchester 13 (July 28).

CHEMISTS (with a four-year University degree in science with chemistry as a major subject; experience in analytical work is essential and a specialized knowledge of pedology or soil science desirable) in the Chemistry Branch of the Division of Agriculture and Lands, Southern Rhodesia Government—The Secretary, Office of the High Commissioner for Southern Rhodesia, 429 Strand, London, W.C.2 (July 28).

RESEARCH OFFICER IN THE ORGANIC CHEMISTRY SECTION, Division of Industrial Chemistry, Fishermen's Bend, Melbourne, to aid with investigations in progress on the chemistry and the refining of cane and other waxes—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 3460 (July 28).

ANALYTICAL CHEMIST (with a degree in chemistry, biochemistry, or agricultural chemistry, preferably with honours) to be responsible for analytical work on grass and grass products, and an ASSISTANT ADVISORY OFFICER IN MYCOLOGY (with an honours degree in botany with specialization in either mycology or plant physiology, or a degree in agriculture with postgraduate study in these subjects)—The Secretary, North of Scotland College of Agriculture, 41½ Union Street, Aberdeen (July 31).

ASSISTANT CURATOR OF THE PATHOLOGICAL MUSEUM (the Keith Museum) of the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (July 31).

CHAIR OF AGRICULTURE at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (July 31).

CHAIR OF PHILOSOPHY in the Faculty of Theology, Royal University of Malta—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (July 31).

CHIEF AGRICULTURAL ECONOMIST (with a specialized degree in agricultural economics) in the Department of Agriculture and Lands, Southern Rhodesia—The Secretary, Office of the High Commissioner for Southern Rhodesia, 429 Strand, London, W.C.2 (July 31).

DEMONSTRATOR IN GEOGRAPHY—The Secretary, The University, 38 North Bailey, Durham (July 31).

INSTITUTION OF GAS ENGINEERS RESEARCH FELLOWSHIP for post-graduate research in gas chemistry—The Registrar, The University, Leeds 2 (July 31).

LECTURER IN ECONOMICS at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (July 31).

LECTURERS or **ASSISTANT LECTURERS** (3) **IN GEOGRAPHY**, to carry out research in climatology and oceanography, historical geography, plant and animal geography, social geography, and field work, with special reference to Malaya and South-East Asia, at the University of Malaya, Singapore—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (July 31).

LECTURER IN CIVIL ENGINEERING, and a **LECTURER IN MECHANICAL ENGINEERING**, at the University of Natal, Durban—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (August 1).

RITCHIE PROFESSOR OF RESEARCH IN ECONOMICS at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (August 7).

VETERINARY OFFICERS and **RESEARCH OFFICERS** in the Ministry of Agriculture and Fisheries—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 130–173/51 (August 9).

LECTURER IN MATHEMATICS at Auckland University College, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (August 15).

SENIOR LECTURER IN FLUID MECHANICS AND HYDRAULICS, and a **LECTURER IN CIVIL ENGINEERING**, at Canterbury University College, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.2 (August 20).

LECTURER IN GEOGRAPHY—The Secretary, The University, 38 North Bailey, Durham (August 31).

ALLEN AND HANBURY'S RESEARCH FELLOWSHIP (applicants must be pharmaceutical chemists or graduates in pharmacy, science or medicine of a university)—The Secretary, School of Pharmacy (University of London), 17 Bloomsbury Square, London, W.C.1 (September 1).

RESEARCH FELLOWSHIP IN THE DEPARTMENT OF ELECTRICAL ENGINEERING, for research in the field of vacuum insulation—The Registrar, Queen Mary College, Mile End Road, London, E.1 (September 1).

LECTURER IN MATHEMATICS at the University of Natal, Durban—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (September 15).

ASSISTANT EXPERIMENTAL OFFICERS (including biologists) in various Government departments and divided between the following main groups and subjects: (*a*) mathematical and physical sciences, (*b*) chemistry and metallurgy, (*c*) engineering subjects, and (*d*) miscellaneous (including geology, library and technical information services)—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting No 3068 (October 1).

CIVIL ENGINEERS, SANITARY ENGINEERS and **STRUCTURAL ENGINEERS** in a number of Departments in England and Scotland—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting No. 3405.LA (December 31)

ASSISTANT ENGINEER in the Public Works Department, North Borneo—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting No 27322/48.

ASSISTANT LECTURER IN THE SCHOOL OF PHYSICS AND ALLIED SCIENCES—The Registrar, College of Technology and Commerce, The Newarke, Leicester.

BIOCHEMIST to carry out research and other routine work in the Institute of Medical Research, Federation of Malaya—The Director of Recruitment (Colonial Service), 2 Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting 27106/49/51.

CIVIL ENGINEER (Ref. No 27322/211), and a **MECHANICAL ENGINEER** (Ref. No. 27333/39), to the Jamaica Government Railway—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting the appropriate Ref. No.

DEMONSTRATOR IN BOTANY at the School of Agriculture, Sutton Bonington—The Registrar, The University, Nottingham.

DEVELOPMENT GROUP MANAGER (with a good honours degree in chemistry, physical chemistry or physics, associateship of the Royal Institute of Chemistry or the Institute of Physics, or equivalent qualifications) at the Ministry of Supply Factory, Division of Atomic Energy (Production), Capenhurst, Chester, to take charge of an applied research and development laboratory engaged on special development work for a new atomic energy project—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs.

ELECTRICAL ENGINEERS in the Electrical Engineering Department of the Admiralty—The Admiralty (C.E H., Room 88), Empire Hotel, Bath.

EXECUTIVE ENGINEER in the Department of Works and Hydraulics, Trinidad—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting No. 27322/16.

HORTICULTURAL PRODUCTION AND MARKETING OFFICER—The Controller, Land Settlement Association, 43 Cromwell Road, London, S.W.7, endorsed 'H.O.'.

INSPECTORS OF AGRICULTURE (4) in the Ministry of Agriculture, Sudan—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Inspector of Agriculture—4/11'.

INSPECTORS OF MINES in Malaya—The Director of Recruitment (Colonial Service), Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting No. 27099/5A.

INSTRUMENT ENGINEER (with an honours degree in engineerin corporate membership of one of the Institutions of Mechanical Electrical Engineers, or equivalent qualifications) at Windscale Work Sellafield, Cumberland, to be responsible for the supervision of wor shops engaged in the construction, installation, maintenance, repa and calibration of a wide variety of instruments—The Ministry Supply, Division of Atomic Energy (Production), Risley, Warringto Lancs, quoting WD.2/1.

LECTURER IN MECHANICAL ENGINEERING—The Secretary an Registrar, University College, Southampton.

LECTURER IN METALLURGY—The Registrar, University Colleg Singleton Park, Swansea.

LECTURER IN PHYSICS—The Principal, North Staffordshire Technic College, Stoke-on-Trent.

PROFESSIONAL ENGINEERS, General Service Class (Main and Seni grades), in the Admiralty and other Government departments—T Secretary, Civil Service Commission, Trinidad House, Old Burlingt Street, London, W.1, quoting No 8.86/51.

SENIOR SCIENTIFIC OFFICERS and **SCIENTIFIC OFFICERS** in vario Government Departments and covering a wide range of scienti research and development in most of the major fields of fundament and applied science—The Civil Service Commission, Scientific Bran Trinidad House, Old Burlington Street, London, W.1, quoting No. 39

SONICS SCIENTIST (physicist or biophysicist with Ph.D. degree, goo grounding in acoustics with two or more years experience in soni research, British) to be responsible for a sonics section with a staff several junior scientists—The Director of Research Personnel, Defen Research Board, Department of National Defence, 'A' Buildin Ottawa, Ont., Canada, quoting Competition G-8.

WORKS MANAGER (with either *a*, an honours degree in engineerin or corporate membership of the Institution of Mechanical or Electric Engineers, or *b*, an honours degree in chemistry or physics and ass ciateship of the Royal Institute of Chemistry or the Institute of Physic at the Ministry of Supply Factory, Division of Atomic Energy (Pr duction), Capenhurst, Chester, to be responsible for the operation of large chemical engineering plant engaged in the production of atom energy material—The Ministry of Supply, Division of Atomic Energ (Production), Risley, Warrington, Lancs, quoting 'CB/3'.

PLANNING AND LAND UTILIZATION

THE progress report by the Ministry of Local Government and Planning* on the work of the Ministry of Town and Country Planning from its establishment in February 1943 until it was merged in the Ministry of Local Government and Planning in January 1951 touches on numerous matters of direct interest to the scientific worker. There is a most readable account of the way in which the establishment of the Ministry arose out of the unsuccessful attempts in the previous twenty years to deal with planning problems permissively and piecemeal, and out of the consistent recommendations of the Barlow, the Uthwatt and the Scott Reports in favour of a central planning authority. The legislation of these eight years, during which five major Acts were passed, is then reviewed, and, in particular, the difficulties of the Town and Country Planning Act, 1947, are explained, and the present organization for planning is outlined; the second part of the report deals broadly with local and regional planning and is at pains to show how development control operates, the position in regard to compensation and the reasons why progress in some respects has been so slight.

This lucid exposition of the work and policy of the Ministry explains many of its actions if it does not always justify them; but the major effect of such a stock-taking is to raise more fundamental issues, and on the chief of these the report is silent. It refers, for example, to difficulties which the local authorities encountered and stresses their new powers and responsibilities; but it ignores the important factors which are eroding the whole structure and spirit of local government and which were emphasized in a recent debate in the House of Lords on April 25. Although the report admits that town planning has few positive achievements to its credit as yet, the Ministry still appears to be confident that such achievements will be possible in the future. But the question whether the capacities of the Ministry really match its powers is never faced. Indeed, this survey leaves the answer to that question in some doubt. Many of the factors that have held up progress have been due to causes outside the control of the Ministry; but on the evidence of this report, the Ministry has sometimes failed to appreciate the meaning of effective priority. Moreover, when achievement is small, the question is inevitably asked whether the large machinery set up and engaged in the routine administration of planning controls is yielding a social dividend. If it is not doing so, and is not seen to be doing so, a clear answer must be forthcoming to the question what the public is getting in exchange for its money and for the disturbance which the planning authorities, and with them the Central Land Board, are causing.

Further, the really fundamental issues raised in the third part of the report, which deals with planning problems of national importance, are not adequately discussed. Technical problems intrude to a limited extent into the discussion of local and regional problems in the second part of the report; but in the main it is with this third part that scientific workers will be most closely concerned.

---

* Town and Country Planning 1943–1951. Progress Report by the Minister of Local Government and Planning on the Work of the Ministry of Town and Country Planning. (Cmd. 8204.) Pp. vii+215. (London: H.M. Stationery Office, 1951.) 5s. net.

First among these problems is that of the conflicting claims on land. Here again the report gives a reasonable account of the way in which the attempt is made to discharge the most important and difficult responsibility of the planner: that of balancing, and, where possible, reconciling, the rival demands between agriculture and other forms of development so as to secure that land is used in the best interests of the community at large. There is, it is emphasized, little more than half an acre of food-producing land in Great Britain for each member of the population, and the amount of improved farm-land also represents roughly the amount of land which, being well-drained and fairly level, is most suitable for development.

The report points out that it is a healthy sign of a more realistic attitude to agriculture that inroads upon agricultural land to-day provoke outspoken criticism; and on the showing of this report the Ministry has been more successful than is frequently supposed in resisting claims that conflict with the wider national interest. Particularly in dealing with the demands of the Services, the Ministry has been able to secure the withdrawal of a large number of important proposals. The record of its activities given in this chapter of the report deserves to be widely known; for it presents the broadest picture of the whole situation that is conveniently available. The question of mineral extraction and the restoration of land is dealt with in a subsequent chapter; but otherwise the picture is fairly complete. Industrial development, agriculture, transport, the hydro-electric schemes, water supply, housing, schools and playing fields—the demands which all these make for land are passed in review, and generally speaking it would appear that the situation is much more satisfactory than might have been expected in view of the failure to implement certain of the recommendations of the planning reports mentioned earlier.

Certain main features in the present situation are well indicated; but not all of them receive full attention. Stress is rightly laid on the importance of new proposals, such as hydro-electric schemes, being discussed with the local planning authorities while it is still possible to modify them. Nothing, however, is said as to the importance of such projects being considered—and at an early stage—in relation not merely to conflicting claims on the land but also to other schemes in the same field. Particularly in regard to the Services claims for land, some of the hydro-electric schemes and the projects for water-supply, there is reason for doubting whether the possibilities in regard to co-operation or alternatives have been properly explored or even considered before advancing some of the proposals. Few if any of the water undertakings have faced the plain fact that unless steps are taken to deal with the waste of water, all the possible gathering grounds of Britain will be insufficient to meet the demand within a few decades, even if agriculture and every other interest are entirely disregarded.

Nor is there anything in this report which brings out adequately the Ministry's anomalous position. Where the demands for land come from other government departments, it is one among others in attempting to adjudicate, and may even be placed in the invidious position of attempting to judge its own case. The predilection of the Service departments and other departments to do this is one cause of the bitterness with which their claims for land are received and discussed, and the Ministry should not be placed in such a position. It might, indeed, reasonably be reponsible for attempting to secure agreement between departments in the light of government policy for the particular region concerned or the country as a whole, and it might even be responsible for seeing that the national point of view is adequately presented to the interdepartmental committee which is called upon to resolve any continuing clash of opinion. It cannot fairly be responsible for decision.

Although the existing arrangement has worked somewhat better than might have been expected, there have been some unwelcome reminders of late that the situation is not without its dangers. One case, not mentioned in this report, is the new afforestation plan of the Forestry Commission for the Quantocks, reasoned objections to which, on scientific grounds as well as on those of amenity, have been advanced by a local society, the Friends of Quantock. The area is also one which was expected soon to become a detached part of the Exmoor National Park. A War Office scheme for a training area for Territorials at Upper Hulme, between Leek and Buxton, also conflicts with the purpose of the Peak District National Park, and threatens a breeding ground of rare birds; while at the other side of the same National Park a tentative proposal for a reservoir threatens the whole Edale valley.

A fresh threat to Braunton Burrows has also been raised by the War Office application to use this area for training in combined operations (see *Nature*, June 2, p. 869). The scientific importance of this area was indicated in a note in *Nature* so long ago as November 30, 1946; that the area should again be in dispute testifies to the unsatisfactory character of the present arrangements for dealing with such claims, and to that weakness in the Ministry of Local Government and Planning which the present survey tends to ignore. The Ministry's main function in interdepartmental discussions is to see that due weight is given to all conflicting factors, and, until the Nature Conservancy was established, the Ministry was spokesman for the interests over which the Conservancy now watches. It remains to be seen whether such scientific interests will be more effectively pressed by the Conservancy.

When all credit is given to the Ministry for its success in the field generally, on the evidence of this report alone some much more effective means is required for dealing with the claims of government departments, notably where the Services or mineral workings are concerned, and for ensuring that there is proper consideration within departments before the discussion reaches interdepartmental level at all. There is no evidence that the Minister of Defence has attempted to secure co-ordination of the demands of the three Services for land for training purposes or proper co-operation in the use of the land allocated to them; a similar situation appears to exist in regard to mineral working. This question is discussed in some detail in the next chapter of the report. Here again little objection is possible to what is postulated as the main objectives in any policy which is to reconcile industry's need for raw materials with other claims on land, or even to the steps which are regarded as necessary to implement that policy. It is essential to see that mineral working, while meeting industrial needs adequately, does not waste land, interfere with agriculture or damage amenity, and that it is properly integrated with building and other necessary surface uses. That involves, in turn, keeping important mineral deposits available for extraction by preventing surface development that might unnecessarily sterilize them, and also ensuring that suitable deposits are available to mineral undertakers in accordance with the national need.

The doubts that arise in this matter are rather as to whether the steps already taken are sufficient to achieve the desired results, particularly since the provisions of the Mineral Workings Bill for the restoration of land devastated by mineral workings apply only to specified counties and to opencast workings. This exclusion of other mining appears to be unsound; and although according to this survey the Ministry of Fuel and Power consults the Ministry of Local Government and Planning before sites are requisitioned, there is no assurance that this practice will continue or that there is any effective means at present of restraining the Ministry of Fuel and Power from judging its own cause.

Despite, therefore, the examples of successful representations quoted in this report, we cannot rest content with the steps already taken. It is not sufficient for all mineral workings to be brought completely under planning control, and for the Government to take its appropriate place in the planning of mineral workings. It will be little better placed than local authorities to relate particular questions to long-term needs unless it possesses far wider knowledge of both the geological and the industrial aspects of mineral production. Basic information on the economics of production and distribution and of the detailed requirements were lacking, as well as facts about the distribution within known deposits of economically valuable material and its physical and chemical qualities, when mineral extraction first came under effective planning control.

Research into these problems is the first essential, and should be undertaken as a matter of urgency. The absence of the basic information makes nonsense of the suggestion in this report that the responsibility of deciding that certain areas shall not be worked for minerals must carry with it the obligation to ensure that suitable areas are selected for working, and that industry can secure the necessary ownership or working rights. Had the essential information on the economics of working, including restoration, and on alternative sources been available, some of the worst devastation due to opencast coal mining might have been avoided. No lesson of this survey is indeed more emphatic than that of the futility of attempting planning in any positive sense except on the basis of factual knowledge.

Something more is said on this point in the final chapter of the report. Although the research staff of the Ministry of Local Government and Planning includes geologists who are responsible for preparing reports on the minerals essential to industry and on the incidence of the more common minerals won by surface working, it does not appear that expansion of this staff is either contemplated or desirable. The task of the Ministry should be rather to stimulate the necessary investigations by the bodies best equipped for the purpose, such as the Geological Survey, the Department of Scientific and Industrial Research, the universities and so on. The field is one in which an Economic Research Council might have been of invaluable assistance, particularly when co-operating with other bodies such as the Agricultural Research Council.

The activities of the Ministry in regard to the protection of amenity have already been mentioned incidentally; but a separate chapter of the report discusses such problems in general, and in particular relation to the preservation of trees and woodlands, as well as the preservation of buildings and the design and appearance of new buildings. Its responsibilities in regard to national parks are summarized in a chapter which adds little to what was contained in the first report of the National Parks Commission. The account, however, is even more persuasive as to the ability of the Ministry to restrain the departments and other interests from causing irreparable damage to our scenic heritage. Moreover, in confirming, substantially as it was made by the National Parks Commission, the designation order for the Peak District National Park, the Minister for Local Government and Planning not only strongly endorsed the views of the Commission, but also stressed the importance of mutual accommodation between those who live and work in the parks and those who visit them.

The importance of that factor is somewhat obscured in this report and indeed by the very vigour with which Mr. Dalton is implementing the provisions of the National Parks Act. It is all to the good that the establishment of national parks should proceed apace, and that a national park safeguarding the Pembrokeshire coast and the Prescelly Hills should be proposed for this year and one for Brecon Beacons and the Black Mountains next. But there is at least a danger that too much may depend on the interest and personality of the Minister himself, and under Mr. Dalton's successors the Ministry may prove unable to sustain the battle on the same equal terms. It is plain from this report that there is no one man or body equipped with all the factual knowledge on which to base sound decisions as to the right use of land, nor is it easy to visualize such a body when all the necessary fact-finding and research have been completed. The most that can be expected is some means of preventing snap and *ex parte* decisions, in which conflicting claims and long-term interests are ignored. Adjustment of such claims and of short- and long-term interests must of necessity take place at a high level, but this does not imply of necessity a super-planning authority. The Ministry of Local Government and Planning is clearly capable of bringing into the discussions the reasonableness which makes co-operation and adjustment possible, and to that extent has justified its establishment though not necessarily the full extent of its organization. On that side there is room for much clearer thinking; but on the record here presented, the Ministry is entitled to claim the support of all who are concerned to see that the use of the land of Britain shall be determined on the basis of the fullest possible factual knowledge and on the due consideration of all the conflicting interests involved from a national and not from a purely sectional point of view.

TIME AND CLIMATE

Dating the Past

An Introduction to Geochronology. By Prof. Frederick E. Zeuner. Second edition, revised and enlarged. Pp. xviii+474+24 plates. (London: Methuen and Co., Ltd., 1950.) 30*s*. net.

THIS work is a second edition of a book first published in 1945. It opens with a discussion of the methods of dating by tree rings and varves, and their use in establishing a chronology of Neolithic and post-Glacial times. This is followed by a discussion of the correlation and climatic changes of the Old Stone Age. The last eighty pages describe the time-scale for the whole geological column before the Pleistocene, as derived from radioactive considerations, and discuss the rate of evolution. The subject therefore includes diverse fields of the greatest difficulty and complexity. Its proper discussion demands a critical consideration of the whole of archæology and prehistory, a balanced judgment on the most delicate points of statistical theory and some knowledge of astronomy, meteorology and nuclear physics. To say that the author does not possess the necessary knowledge is not a criticism: no one does, least of all the present writer. To pick holes is easy; there are statements that "make one gasp and stretch one's eyes", as, for example, where it is said on page 16, "of 96 sun spots no fewer than 63 have periods between 9·9 and 11·9 years". Such absurdities are probably inevitable in so long and diverse an argument and do not touch the real purpose of the book.

The main theme is that the Croll–Ball–Milankovitch theory of the astronomical cause of ice ages gives an alternation of cool and warm periods that conforms to the facts of archæology. I must confess that I remain unconvinced. An enormous and intricate structure of fact and surmise is presented that at many points fits well with the calculated curves giving the variation of the heat arriving from the sun at the surface of the earth. It is rash for an amateur in these matters to question such a performance; but awkward doubts occur. Why is America dismissed in one page although, "In North America, Pleistocene chronology is, of course, highly developed"? Can it be because it gives little evidence in support of Milankovitch? Is the evidence for three phases of the last glaciation derived from the three buried channels near the mouth of the Thames convincing? There is a channel for each phase, and in a table it looks admirable until one remembers that there are dozens of other buried channels in southern England that are not mentioned.

It may with some justice be argued that a dubious or incorrect principle is better than none, and that, right or wrong, Prof. F. E. Zeuner does provide a framework on which to hang the facts, and does introduce some order into the chaos of prehistory. If the framework is, in fact, wrong, the quickest way to demonstrate it is to hang facts on it until they patently will not fit. In the meantime, it would be difficult to suggest an alternative as detailed that would fit at all.

I think it is impossible for anyone used to the firm ground of physical science, or even to the penumbra of doubt that usually accompanies a geological fact, to read any discussion of prehistoric chronology without a profound feeling of distrust. The mind revolts at such fare. Why should one believe Prof. A. rather than Prof. B. or Prof. Z.? What are the criteria? What is fact and what is wishful thinking? If one is told bluntly that Korn has observed a "sunspot cycle" of 11·5 years in the thickness of the varves in the pre-Cambrian Nama beds in South-West Africa, does it mean that the matter is beyond reasonable doubt? After looking at Korn's paper, I am very doubtful of the existence of any real periodicity, and certain that the point has not been established. The correlation of varve and tree-ring sections and the extraction of periodicities from them are statistical questions involving series the terms of which are not independent. It is remarkable that the great developments in the theory of such series in the last ten years have not been applied in this field. Arguments based on the assumption that the terms must either be independent or be governed by 'periods' can never be convincing. There seems to be a firmly planted instinct in the human mind that wishes to find periods in autocorrelated series, and there is no subject in which there is a greater danger of error. The weakness of Prof. Zeuner's argument in this respect is not to be laid at his door; the subject has just not been developed in a satisfactory manner. In some matters he shows more caution than his predecessors; in particular, he expresses a well-founded disbelief in the teleconnexion of varve series.

In spite of all these doubts and uncertainties, Prof. Zeuner's book does serve a most valuable purpose. It brings together in a coherent way a great body of knowledge and sets it out in such a manner that everyone can see how defective our understanding of it is. The next step in the solution of the difficulties probably lies with the physicist, the chemist and the oceanographer, and for them an easily digested summary such as this is invaluable. It is likely that in the next ten years work on radioactive carbon, on the distribution of isotopes and on ionium in ocean cores will enable us to obtain a knowledge of the changes of temperature in the past and of their dates. It may well be that in his next edition Prof. Zeuner will be able to give some of his dates and correlations as facts. He could then with confidence reverse many of his arguments and use the dates to support his interpretation of the facts. E. C. BULLARD

MATHEMATICS OF NON-LINEAR VIBRATIONS

Nonlinear Vibrations in Mechanical and Electrical Systems

By J. J. Stoker. (Pure and Applied Mathematics, Vol. 2.) Pp. xix+273. (New York and London: Interscience Publishers, Inc., 1950.) 40s.

Contributions to the Theory of Nonlinear Oscillations

By S. P. Diliberto, L. L. Rauch, F. H. Brownell, M. L. Cartwright, J. G. Wendel, C. E. Langenhop, A. B. Farnell, W. Wasow. Edited by S. Lefschetz. (Annals of Mathematics Studies, No. 20.) Pp. ix+350. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1950.) 14s. 6d. net.

FOR more than two hundred years mathematicians have studied the properties of linear differential equations. In many problems, such as that of pendulum motion, where the equations are really non-linear, the linear approximations give a sufficiently good idea of what actually happens. However, engineers knew that many oscillatory mechanical devices had properties not explicable by the linear approximations; but until comparatively recently, these devices were small and inexpensive, and the easiest way to investigate them was by constructing and operating them. But now, in these days of aircraft, guided missiles and automatic chemical-process plants, it is an economic necessity to calculate in advance the possibly troublesome phenomena which may arise from the vibrations being non-linear. This work was at first undertaken chiefly by engineers and physicists. Now the pure mathematicians, especially in the United States and the U.S.S.R., have realized their opportunities in this field. They are pleasantly surprised to find how important the classical work of Poincaré, Hill and Mathieu turns out to be as a starting-point in attacking the new problems.

An excellent introduction to the subject is given by the first book, that by Prof. J. J. Stoker, whose lucid exposition gives continual references to particular mechanical or electrical systems from which arise the differential equations considered. The first chapter recalls the properties of linear vibrations. The second and third deal with free vibrations when the restoring force is non-linear, using a graphical discussion of the energy curve in the displacement–velocity plane, in which the time is taken as a parameter, and Poincaré's discussion of singular points is of fundamental importance. These methods, however, cannot be used when the time occurs explicitly in the differential equations, as for forced motion. The fourth chapter gives Duffing's apparently unnatural method for dealing with these problems, a method which succeeded when all straightforward approaches, even that of Rayleigh, had failed. This chapter includes also a number of useful analytical methods, in particular those of iteration and perturbation, and ends with a table showing some contrasts between linear and non-linear vibrations. The fifth chapter deals with non-linearity in the damping, which is responsible for 'self-sustained' oscillations, such as occur in radio valves, and in the 'flutter' of aircraft wings. The collapse of the Tacoma bridge is generally ascribed to these oscillations. A special analytical method for such problems was devised by Van der Pol, and this has been used extensively in the U.S.S.R. Other methods are due to Andronow and Witt, and to Miss Cartwright and Littlewood. It is rather surprising that the sixth chapter should deal with *linear* differential equations with periodic coefficients, but these are necessary for discussing the stability of non-linear oscillations. The classical results of Hill, Floquet and Mathieu thus gain a new importance. The appendixes give a rigorous mathematical justification of methods used in the main part of the book, which can be warmly recommended to engineers, physicists and mathematicians.

The second work under review is a collection of monographs edited by Prof. S. Lefschetz and will appeal chiefly to mathematicians engaged in research on the theoretical aspects of the subject, though many of the problems have a physical origin. S. P. Diliberto discusses some general questions connected with Poincaré's results; L. L. Rauch deals with a differential equation of the third order arising from a problem concerning radio valves; and F. H. Brownell investigates the oscillatory solutions of a difference-differential equation, such as arise in control problems. The longest paper is by Miss M. L. Cartwright, and deals with forced oscillations. Similar problems are treated in a different way in papers by J. G. Wendel, by C. E. Langenhop and A. B. Farnell, and by W. Wasow. This volume, like other Princeton University publications, deserves careful study by research workers.

H. T. H. PIAGGIO

MECHANICAL PROPERTIES OF METALS AT HIGH AND LOW TEMPERATURES

The Properties of Metallic Materials at Low Temperatures

By P. Litherland Teed. (Monographs on Metallic Materials, published under the authority of the Royal Aeronautical Society, Vol. 1.) Pp. viii+222. (London: Chapman and Hall, Ltd., 1950.) 21s. net.

Properties of Metals at Elevated Temperatures

By George V. Smith. (Metallurgy and Metallurgical Engineering Series.) Pp. x+401. (London: McGraw-Hill Publishing Co., Ltd., 1950.) 59s. 6d.

THE wide temperature range, some 1,100 deg. C., over which the engineer is concerned with the mechanical properties of metals and alloys is covered by these two volumes.

"The Properties of Metallic Materials at Low Temperatures" is the first of a series of monographs to be published under the authority of the Royal Aeronautical Society, and contains a survey of existing knowledge regarding the non-ferrous metals and their alloys, and the steels. The bringing together of this information is justified not only in connexion with the construction of planes for high-altitude flight, but also by the increasing use of low temperatures by the chemical engineer. Chapters are devoted to a consideration of the major mechanical properties of aluminium, iron, magnesium, copper, nickel, zinc, tin and lead and their alloys, about one-half being devoted to the plain carbon and alloy steels. The author points out that the variations of properties at very low temperatures are as yet unpredictable, and makes the further most pertinent point that the fruits of long and careful work are too often wasted as a result of inadequate description of the composition, and the mechanical- and heat-treatment of the samples investigated.

The treatment in the second work, "Properties of Metals at Elevated Temperatures", differs considerably, in that almost half of the book is devoted to a more-or-less fundamental discussion of plastic deformation in general, both in single and polycrystalline material. A not inconsiderable proportion of this is concerned with room-temperature properties and behaviour, although the effects of higher temperatures do come in for consideration. This section provides an admirable introduction to the mechanical properties of metals, but appears, in places at any rate, to have no very direct connexion with the real subject of the book. Following this introduction is a chapter on high-temperature tests and the equipment employed, after which are discussed the effects of chemical composition on creep behaviour, of manufacturing variables, varying temperature and load, scaling and microstructural changes at high temperatures—the latter particularly dealing with the stainless steels—and a final chapter on design for service at elevated temperatures. A most useful series of nearly five hundred references to original work is given, and an appendix deals with "super-alloys", that is, materials with the highest (as yet) available strength at elevated temperatures. A very great deal of work has gone into the preparation of this most useful account, which has the added advantage that it provides a satisfactory summary of work done throughout the world, and not only in the United States.

Both these volumes can be recommended to the attention of all metallurgists and engineers who are concerned with the mechanical behaviour of materials at temperatures either below or above the normal.

F. C. Thompson

ELECTRONIC DEVICES

Voltage Stabilizers

By F. A. Benson. Pp. 125. (London: Electronic Engineering, 1950.) 12*s.* 6*d.*

The Industrial Applications of Gasfilled Triodes (Thyratrons)

By R. C. Walker. Pp. xi+325. (London: Chapman and Hall, Ltd., 1950.) 40*s.* net.

THE use of electronic devices in instruments and machinery of all kinds is becoming ever more widespread, both in industry and in the laboratory. Such apparatus is often designed by those who have only a very general training in electronics, and there is thus a great need for monographs on specialized applications to which one can turn for a more detailed description than can be found in general text-books, all the more so since the published literature covers a wide range of scientific and technical journals. Such monographs fall naturally into two classes: those which describe the different types of circuits devised to perform similar functions, and those which describe the different applications of a given circuit element.

"Voltage Stabilizers", which is based on the author's recent series of articles in *Electronic Engineering*, falls into the first of these two classes. In addition to dealing with the conventional types of A.C. and D.C. stabilizing circuits embodying saturated-core transformers, glow tubes and hard-valve circuits, some of the newer and less orthodox non-linear circuit-elements are briefly treated. I found the chapter on glow-discharge tubes particularly valuable, since a large amount of data on the stability of different British and American tube-types is collected here.

"The Industrial Applications of Gasfilled Triodes" is the latest of Walker's monographs and deals with the many different applications, not only of thyratrons but also of other grid-controlled gas-filled tubes. Like the author's two previous volumes, it should prove useful in suggesting ways in which problems of automatic control and measurements can be solved. It is a pity that the relatively high price may keep this book away from many laboratory bookshelves.

An important feature of monographs is necessarily an extensive bibliography, and both books are well served in this respect, although in "Voltage Stabilizers" one would have appreciated a classification of the references given at the end of the book.

U. W. Arndt

PASTEUR

Louis Pasteur, Free Lance of Science

By René J. Dubos. Pp. vii+418. (London: Victor Gollancz, Ltd., 1951.) 18*s.* net.

DR. RENÉ DUBOS is already well known to scientific men as the author of two valuable books, namely, "The Bacterial Cell" and "Bacterial and Mycotic Infections in Man". He has now written a book which has a much wider appeal and will be enjoyed by all who are interested in biological science and its development. No new information about Pasteur or his work has recently come to light; but it is interesting to have a book about a great man of science written after a considerable period of time has elapsed since his death, so that his influence upon progress can be critically examined.

Dr. Dubos is a Frenchman who is engaged in bacteriological research, and is especially well fitted to write about Pasteur's life and work. There is a vitality and enthusiasm in the presentation which suggests that as he studied the information existing about Pasteur, he was caught by the brilliance and importance of Pasteur's achievements, and could not rest until he had set down the whole story as he saw it and as he thought it should be told. It is not a simple biography, for it deals with the historical background which made Pasteur's discoveries possible, and with the philosophical implications of Pasteur's pronouncements. It is the work of a critical man of science who wishes to appraise correctly the scientific value of a man's work, and to try to discover whether his successes were due to the times as much as to the man, and if more to the man, to what especial characteristics.

This approach has resulted in a very interesting book which will not only be appreciated by scientific men, but also by the growing number of individuals who are to-day interested in scientific discovery, in how it comes about, and how it affects the life of the community.

The broad outlines of Pasteur's life and work are probably known to many, and the use of words such as 'vaccines' and 'pasteurization' keeps him always in mind. The historical background of the times in which he worked, and the intensity of purpose, hard work and self-denial which he had to exercise in order to overcome the many difficulties and to achieve success, may well be forgotten. All is clearly set down, and the greatness of Pasteur is vividly brought home to the reader.

It is a book which can be read and re-read with enjoyment and profit.

Cytology and Cell Physiology

Edited by Geoffrey H. Bourne. Second edition. Pp. xvi+524. (Oxford: Clarendon Press; London: Oxford University Press, 1951.) 50*s*. net.

THE second edition of this important book is to be welcomed, even though nothing like a coherent view of protoplasmic activity can yet be obtained from it. It is also perhaps to be kept in mind that its effective date is not 1951 but more nearly July 1948, as indicated by the preface. Even so, a great deal has happened since before the Second World War (the effective date of the first edition was 1941). Somewhat ironically perhaps, the most buoyant expressions of optimism regarding imminent progress to be expected in the next decade have been reprinted without change in the least emended chapters. On the other hand, where opportunity has been found for incorporating a large body of new matter, the usefulness to the reader of the subjects discussed has been very greatly enhanced. This concerns especially Schulman's chapter on monolayers, White's on cytogenetics, Bourne's on mitochondria and Golgi bodies, Ludford's on pathology, and Blaschko and Sanders's revision of the chapter on intracellular enzymes.

Two new chapters on histogenesis in tissue culture and in evolution respectively, by Fell and by Willmer, introduce aspects of normal (as opposed to pathological) histology in animals. At the other end, two additional introductory sections by Sanders and Barer, respectively, deal with some of the very powerful new technical developments such as phase-contrast microscopy, electron microscopy and the reflecting microscope. A certain amount of repetition has resulted from such a considerable insertion of new matter, and there are also a few distressing misprints, such as the quotation of 1300 A. as a wave-length of the infra-red (p. 71). Some of the new references mentioned in the text are omitted from the bibliographies.

These are, however, minor defects. On balance, the changes have been very beneficial, and though no single reader is likely to be equally concerned with the whole contents of the book, the great variety of recent bibliographies collected together under one cover is probably one of its most valuable features.

The Littoral Fauna of Great Britain

A Handbook for Collectors. By Dr. N. B. Eales. Second edition. Pp. xvii+305+26 plates. (Cambridge: At the University Press, 1950.) 20*s*. net.

THE second edition of Dr. N. B. Eales's well-known student's book of sea-shore animals has four additional pages devoted to examples of practical exercises in quantitative distribution on sandy and on rocky beaches. These pages are inserted in the appendix, leaving the main pagination unchanged. Some useful descriptions of eggs and egg capsules have been added here and there, and there are other small additions. Thus, *Elminius modestus* appears in the section on cirripedes, and the magnesium chloride method of narcotization has been added to that on preservation. The price of the book has been substantially increased.

In compiling this book the author was faced with a task from which most would have shrunk. One cannot but admire the way in which she has collected and set out an immense amount of most useful information on the classification, external anatomy—and, to a small extent, ecology—of most common and many uncommon shore animals and provided keys to help with their identification. There is no doubt, too, that this unique compilation is well liked—and justly so—by students attending courses in marine biology, although it probably covers more adequately the fauna at Port Erin than elsewhere, in spite of the inclusion of many species not recorded for that locality. The problem of selection must have been one of great difficulty, and it is only to be expected that it is not as successful for some localities as for others. Some groups receive relatively full treatment (for example, decapods, molluscs, echinoderms and fishes), mention being made of almost all species likely to be found on British shores, and quite a few from the region immediately beyond. Other groups, however, are not so completely covered. The treatment of the polychætes, for example, is inadequate for the south-west of England and, at Plymouth, often leads astray students who ignore the author's own instruction to consult the appropriate monograph for final identification. The inclusion in a future edition of another twelve or eighteen common Plymouth shore polychætes would do much to put this right. The section on amphipods could also be enlarged with advantage.

D. P. WILSON

Flora of the Land of Israel

Iconography. By Naomi Feinbrun and Michael Zohary. Pp. 12+50 plates. (Jerusalem: *Palestine Journal of Botany*, Hebrew University, 1949.) n.p.

THIS is a series of line drawings from living specimens portraying quite effectively a selection of Palestinean plants, mostly on a life-size scale. In addition to the habit, botanical details for some of the species are also illustrated. The collection is a miscellaneous one, and indeed no less than twenty-seven families are represented on these fifty plates. There is no obvious basis of selection; but, since the authors refer to this as a first step towards an iconography of the local flora, one may anticipate that it is but an instalment of what is intended ultimately to be a complete series.

Several of the figures represent endemics of Palestine, including three species of *Iris*, namely, *I. atropurpurea*, *I. mariae* and *I. nazarena*, the liliaceous *Bellevalia desertorum*, and *Orchis galilæus*. The brief accompanying notes furnish some morphological and other data, as well as indications of the distribution; but diagnostic botanical characters would have been a welcome addition, and the value of such would have been enhanced as the work proceeds and more species are added in the different groups.

The drawings mostly convey an excellent idea of the character of the species, and some, as, for example, those of the wild *Cyclamen persicum* and *Bellevalia flexuosa*, are exceptionally lifelike; only a few, such as those of *Ceterach officinarum* and *Oxalis cernua*, conspicuously fail to do justice to their subjects,

E. J. S.

Colours

And How we See Them. By Dr. H. Hartridge. Pp. xi+158+12 plates. (London: G. Bell and Sons, Ltd., 1949.) 15*s*. net.

THE six chapters of this book are mainly the content of the six Christmas lectures for children given by Prof. H. Hartridge at the Royal Institution in 1946. The treatment is therefore necessarily popular and approximate, designed to keep within the comprehension of a juvenile audience. It cannot, therefore, be subject to the same criteria of criticism as a book professing to be an authoritative guide to serious students. Nevertheless, Prof. Hartridge has accomplished the task he set himself extremely well, and the lectures have been turned into a very readable account of an interesting and fascinating subject. Anyone desiring an introduction to the problems and phenomena of colour and colour-vision could not do better than read this book, which can scarcely fail to afford pleasure in the reading or to leave an abiding interest which will induce him to extend his study to the less elementary and more rigorous literature in which the subject abounds.

Although, as already indicated, the advanced worker on colour will not look here for guidance on theory, science teachers and lecturers will find the book a mine of useful information on effective and fascinating lecture demonstrations, especially demonstrations by projection. Many teachers, even in universities and technical colleges, fail lamentably in giving life and interest to the study of light by adequate demonstrations of an arresting character. Prof. Hartridge has included in the book descriptions of many of the excellent demonstrations which illustrated his lectures. These cover many branches of the subject, and most of them require only simple apparatus which should not be difficult to improvise, even from the resources of a school physics laboratory.

The book is well printed in easily legible type. The illustrations include portraits of Sir Isaac Newton (frontispiece) and Thomas Young. There are many line diagrams and twelve coloured plates. The diagrams, on the whole, are good, except in a few cases where simplification has been carried beyond tolerable limits. The colouring of the plates is rather crude; but this is not likely to mislead the reader.

J. GUILD

A Camera in Antarctica

By Alfred Saunders. Pp. 160 (72 plates). (London: Winchester Publications, Ltd., 1950.) 21*s*. net.

THIS book, a record of fifteen years of photographing in the Antarctic, is noteworthy for its really magnificent collection of illustrations. Whether he is showing his reader 'close-ups' of bird or animal, or of scenery, Mr. Alfred Saunders contrives to excel, not only as a photographer but also as an artist. The general standard is so high that it is not easy to single out illustrations, but there is on p. 70 a remarkable photograph of the wanderer albatross. This great sea-bird has a wing span of twelve feet, which, incredible as it may seem, is almost double the wing span of the male golden eagle. The eggs of the wanderer albatross, we are told, weigh 1 lb. and are good eating; only one egg is laid. The Antarctic summer is too short for the growth of the young albatross, which remains in the nest unfledged throughout the winter with its blizzards and severe frosts. It is supposed that during the winter the parent albatrosses do not visit their young, which subsist on their accumulated fat; but Mr. Saunders believes that they do occasionally return and feed the young.

There is a truly remarkable series of photographs of the various Antarctic penguins, and we are shown one of an Adelie penguin being pushed by its large chick during feeding operations to the very edge of a 600-ft. precipice. The author mentions that one day he saw two penguins which had evidently fallen over this cliff. They appeared almost lifeless, and, a few feet away, Skua gulls were waiting for them to die. Yet when he visited the place the following day he found the penguins had almost recovered, and were actually walking about. That a flightless bird should survive after a fall of 600 ft. is almost incredible, especially when the descent ended not on the water but on rocks.

SETON GORDON

The Biochemistry of the Nucleic Acids

By Prof. J. N. Davidson. (Methuen's Monographs on Biochemical Subjects.) Pp. ix+164+4 plates. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1950.) 7*s*. 6*d*. net.

PROF. J. N. DAVIDSON's little book, the first of a new series of 'Methuen Monographs', was published last autumn and has already proved its value to both research workers and students. It gives, in a short space, a very fair account of the chemistry and properties of the nucleic acids, leading to a fuller account of what is known of their function and metabolism. It is remarkable how much recent research he has managed to include in a small book. Although, as he points out in the preface, significant advances have been made since the book went to print and will no doubt continue, yet, broadly speaking, the emphasis is on recent work, and the serious student will find it an excellent introduction to the many researches which are going on.

It is a very remarkable fact that, although a close connexion with the processes of reproduction is suggested by the presence of nucleic acids in the chromosomes and in various particles which are known or suspected to be self-reproducing, and also by the close correlation between the onset of nucleic acid synthesis and the start of the mitotic cycle, no real clue has come to light as to their real function. Many workers have studied these compounds in the belief that they may perhaps discover in them the molecular nature of the gene, yet so far no one has been able to suggest a plausible method by which they could act in this way. All those biologists as well as chemists who want to know the real facts of the case could not do better than study this account.

The Complete Garden Handbook

By Maron J. Simon, John Elliott, Dickson W. Pierce and Beatrice P. Hendrix. Pp. xii+451+32 plates. (New York: D. Van Nostrand Co., Inc.; London: Macmillan and Co., Ltd., 1950.) 37*s*. 6*d*. net.

THE aim of the authors of this comprehensive volume is to give "information on every topic of interest to the gardener, including planning the garden, choosing flowering plants, shrubs and trees, and every step in practical gardening". It is designed for American readers and will no doubt be welcomed by them for its completeness and handy size. It is inevitable that many of the terms used sound strange to British ears, and it is to be hoped that the American habit of telescoping plant names wherever possible (for example, "Morningglory") will not spread across the Atlantic. The volume is lavishly illustrated in colour; but, it must be said, the standard of the plates, both in design and execution, is very low. It is difficult to imagine what value there could be in a picture, however good, of a single, unnamed, daffodil flower; but when this appears (Plate 11*B*) as an unrecognizable yellow 'star-fish' against a bright blue sky, the result is deplorable, and the majority of the plates are of much the same standard.

J. S. L. GILMOUR

HYPOTHESES RELATING TO THE BRAIN–MIND PROBLEM*

By PROF. J. C. ECCLES, F.R.S.
Department of Physiology, University of Otago, Dunedin

FOR the purpose of this article the use of the term 'mind' will be restricted to 'conscious mind' in all its general operational field of perceiving, thinking, willing. As such, mind is a fact of experience, though for each of us only our own mind is an observable. It has been argued that the private and restricted nature of the observation eliminates mind from that class of observable phenomena which are publicly observable and hence by general agreement regarded as facts of experience. But all observation is, of course, just as private and restricted, the public character being given by symbolic communication between observers, in particular through the medium of language. The private observation of conscious mind in this manner achieves public status, and may therefore be ranked as a fact of experience. As such, observations relating to mind become a part of the raw material upon which scientific investigation may properly operate.

The Cartesian dualism of mind and matter necessarily involved the problem of how mind and brain could interact in perception and in willed acts. Most philosophers[1-3] now argue that the hopeless difficulties of this problem have rendered untenable both dualism and the interactionist view of brain–mind liaison. On the other hand, many men of science[4-6] find in dualism and interaction the most acceptable initial postulates in a scientific approach to the problem of mind and brain. In such an approach the question arises: What scientific hypotheses may be formulated that bear in any way on the hitherto refractory problem of brain–mind liaison ? It should be noted that such hypotheses would represent an extension of natural science to a field of non-sensual concepts, and even to a field outside the matter–energy system of the natural world, as has been convincingly argued by Sherrington[5]. But also it should be noted that Adrian[6,7] has recently directed attention to the necessity for such an extension.

There are first various subsidiary hypotheses that have already been formulated, most notably by Sherrington[5] and Adrian[7] and which relate merely to the events in the brain when it is in liaison with mind.

(1) Mind liaison with brain occurs primarily in the cerebral cortex, though diencephalic centres may be also concerned, particularly as continued bombardment by impulses therefrom is necessary for sustaining activity in the cerebral cortex[8-10].

(2) Only when there is a high level of activity in the cortex (as revealed by the electroencephalogram) is liaison with mind possible. Unconsciousness supervenes instantly the activity is lowered (as, for example, in anoxia, anæsthesia, concussion, sleep[11-13]). Dreams are associated with bursts of electrical activity in the electroencephalogram[11].

(3) The uniqueness of each percept is attributable to a specific spatio-temporal pattern of neuronal activity in the cortex[8]. In general, any thought pattern in the mind has a counterpart in a specific spatio-temporal pattern of neuronal activity, which we may call the evocative neuronal pattern.

(4) Memory of all events is dependent on the development and persistence of increased excitatory efficacy across certain synaptic junctions. Lashley[14] has convincingly argued that "the activity of literally millions of neurons" is involved in the recall of any memory. There is a tendency for some particular spatio-temporal pattern of neuronal activity to be evoked by a particular predisposing or triggering neuronal activity and/or excitatory afferent input[8]. The remembered thought appears in the mind as the spatio-temporal pattern is being replayed in the cortex. This hypothesis has been recently supported by the finding that activation of monosynaptic paths in the spinal cord led to prolonged (measured in hours and possibly days) increase in the excitatory efficacy of synaptic knobs rendered specially sensitive by disuse[15]. It may therefore be postulated that the initial development of effectiveness in certain synaptic junctions is a sequel to the primal event that is remembered, and this effectiveness is sustained and even enhanced by each subsequent replaying in the brain (and remembering in the mind).

These four hypotheses relate to one and the other side of the apparently unbridgeable gulf between the matter–energy system of the brain and the 'non-sensual concept' of the mind which has remained unassimilable into the matter–energy system[5]. They describe the specific events in the brain which are linked with specific states in the mind, but say nothing concerning the 'how' of that linkage.

However, there is one partial approach to this key problem that hitherto has not been essayed. We can ask the question: How does it come about that liaison with mind occurs only in special states of the matter–energy system of the human* cerebral cortex ? Is there any special property of this system that places it in a separate category from all the remainder of the matter–energy or natural world and even from its own matter–energy system when it is not in this special state of activity ? It is here contended that such a special property in outstanding measure is exhibited by the cerebral cortex during consciousness, and the hypothesis is developed that the brain by this means enters into liaison with mind, having the property of a 'detector' that has a sensitivity of a different kind from that of any physical instrument. An introductory paragraph giving an outline of the essential structural and functional features of the neurones (nerve cells) of the cerebral cortex provides the necessary basis for an account of this special detector property, but for a full account various reviews may be consulted[8,16-21]. It is assumed that the functional properties of neurones in the cortex are similar to the motoneurones which have been extensively investigated in mammals. This assumption is justified by the essential similarity of structure and function that is revealed by investigations on cortical neurones[8-10,22,23].

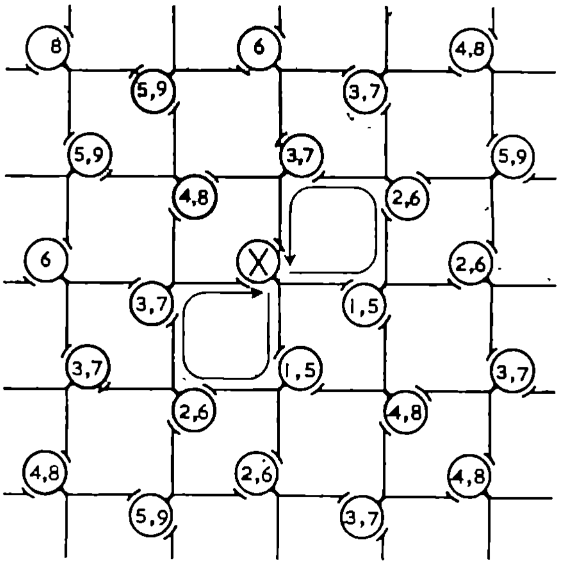
---

* Substance of a lecture given to the Australasian Association of Psychology and Philosophy (Dunedin Branch) on April 12.

* In respect of the existence of rudimentary conscious minds of animals we must remain agnostic, for the essential information is necessarily derived by private observation and cannot be communicated to us by any animal, lacking as it does the means of adequate symbolic communication in language or otherwise.

The human cerebral cortex is essentially an extensive sheet of neurones about three millimetres thick, and with an average population of 40,000 neurones per sq. mm., there being in all about 10^{10} neurones[14]. Each neurone is *functionally* linked to many others by means of minute specialized areas of *contact* (synapses), there being formed in this way a complex functional network of neurones. Scattered over the surface of a neurone that forms a link in this network there are about a hundred synaptic contacts from other neurones, by any one of which it is a recipient of an excitatory influence when that neurone discharges an impulse thereto. When so activated adequately (a sufficient number of impinging impulses in a sufficiently short interval), the recipient neurone in turn generates an impulse which is discharged down its axon and thence exerts a brief excitatory action on the many other neurones (again perhaps about a hundred) by means of the synaptic knobs on its branching axon. After the generation of such an impulse a neurone passes through a depressed phase from which recovery gradually occurs in rather more than 0·1 sec.[11]. During this recovery phase it becomes progressively more susceptible to the excitatory effects of impinging impulses and again generates an impulse at the instant that the summed synaptic excitatory action reaches an intensity matching its excitability. If immediately preceding synaptic excitations have lifted a neurone to a sufficient degree of excitation, an impulse impinging at a synapse on its surface will initiate the discharge of an impulse after a delay of about 0·5 msec. However, if the excitation is at a lower level, then an impinging impulse causes merely a sudden raising of the excitation which, decaying with a half-time of two to three milliseconds, has virtually disappeared in 10 msec. The added complication produced by inhibitory synaptic action will be neglected for the present.

Lorente de Nó[16-18] has shown in diagrammatic form how the contacts obtaining between neurones in the cortex provide a system that could function as a complex net, the various neurones being at the nodes while the strands are woven from their numerous processes (dendrites and axons) that provide the multiple synaptic contacts. But before considering a net of such complexity, where each node is the convergent point of scores of paths and each in turn projects to scores of other nodes, it is useful to consider the properties of the simplest possible net of the type exhibited in the cerebral cortex (see accompanying illustration). Burns[19] has recently shown that the effects produced by electrical excitation of the cortex are explicable in terms of a similar type of net. Each neurone is assumed to have only two excitatory synaptic knobs on its surface and in turn to have an axon which has only two knobs on two other neurones. Further, it is assumed that the synaptic connexions so formed are of a pattern that allow the neurones to be schematically arranged in the rectangular net-like form of the illustration, where it will be noticed that there is virtually radial symmetry from any point, and the possibility of indefinite extension in every direction. If the allowance is three synapses per neurone, a similar construction with radial symmetry (based likewise on alternating direction of transmission, cf. successive rows of the illustration) would be possible in a three-dimensional network—and in general for n synapses per neurone in an n-dimensional network.



It will be seen that even the formalized and simplified neural network of the illustration potentially contains an enormous variety of neural circuits. For example, if neurone X discharges an impulse, the simplest circuits back to X are shown by the arrows, that is, there are two 4-neurone arcs, and next simplest are six 8-neurone arcs. In addition, it is potentially possible for a progressive invasion to spread over the net. The numerals on each neurone give the number of synapses traversed in leading to its first (and second) activation, there being with each a continued arithmetical progression of four due to the return circuits. In the operation of such a network it may be provisionally assumed that a single impulse impinging at a synapse on a neurone is adequate to generate the discharge of an impulse, and the probable value of 1·0 msec. may be assumed for synaptic delay plus conduction time to its own axonal terminals (the axonal length in the human cerebral cortex is very short for the majority of neurones[16-18]). Thus, there are chains with possible circuit times of 4 msec., 8 msec., 12 msec., etc., the so-called closed self-re-exciting chains[17]. Actually, such short circuits would be most improbable on account of the prolonged (at least 0·1 sec.) and deep (for 20 msec. or so) depression that a neurone suffers after discharge of an impulse.

During inattentive, but awake, states the predominating electroencephalogram rhythmic wave (the α-wave) at about ten a second indicates that the most probable circuit time of all those available approximates to 0·1 sec., that is, to the period needed for almost complete recovery of each neuronal element, and, allowing 1 msec. for each link, it would be expected that roughly there would be about a hundred neurones in one such circuit. But to conceive of such an isolated circuit is an abstraction, for, as here illustrated schematically, each link of any one circuit is held in common with a great variety of other circuits. At each neuronal node in the network impulses either may be ineffective excitors and hence be extinguished, or may fuse in their influence (synaptic summation), so generating a new impulse that in turn disperses to other nodes, there likewise to be extinguished or fused. During inattention much of this patterned activity appears to be virtually random, adopting on the whole the dominant α-rhythm[8].

When the brain is active, for example, during perception, mathematical calculation or skilled action, this randomized activity with its approximate synchronization of large groups of neurones is broken up[8]. We may interpret this as due to the formation of specific spatio-temporal patterns of activity in the neural net. Sherrington[5] vividly and aptly pictures this net as an "enchanted loom where millions of flashing shuttles [the nerve impulses] weave a dissolving pattern, always a meaningful pattern, though never an abiding one; a shifting harmony of sub-patterns".

We have in imagination to develop the two-dimensional formalized net of the accompanying illustration to one of many dimensions, each node or neurone being at the confluence of many paths and itself projecting to many other nodes; and at each node the time of discharge is determined by the microscopic spatio-temporal pattern of the synaptic bombardments on its surface from millisecond to millisecond. The excitatory efficacy of the synaptic knobs of any one neurone will be related to its past usage. Hence, in response to certain spatio-temporal patterns of afferent input into the cortex, the developing cortical patterns will to some extent be determined by this developed structural specificity, as has already been discussed in relation to memory. That is, we are envisaging the pattern of activity in the cortex at any instant as being determined by two factors, the immediate (and very recent) input and the developed structural specificity (inherited and acquired). It is to be noted that unconsciousness is an invariable accompaniment of a net that, as shown by the electroencephalogram, is at rest or only active in low degree or active in a driven stereotyped way as in a convulsion of epilepsy or shock therapy, that is, the net as such is not in liaison with mind. Adrian[8] even brings forward evidence that the part of the net giving the α-rhythm is not in liaison with mind. It is important, therefore, to fix attention on the special properties of the neural net during the specific patterned activity (as indicated by a rapid and irregular electroencephalogram) that occurs when there is liaison to mind.

Suppose some small 'influence' were exerted at a node that would make a neurone discharge an impulse at a level of synaptic excitation which would otherwise have been just ineffective, that is, in general to raise the probability of its discharge. Such a discharged impulse would in turn have an excitatory effect on all the other nodes on which it impinges, raising the probability of their discharge, and so on. If we assume, as above, that the spread from node to node occupies 1 msec., then even on the two-dimensional net of the illustration a spread to a large number of neurones is possible in, say, 20 msec., a time that is chosen because it is at the lower limit of duration of discrete mental events. It is to be remembered that the neurones of the network are at a high level of excitation, as there is initially a large amount of circulating activity (impulses) in the network. Potentially the number of neurones that could be involved would be given by the formula: $2m^2 - 2m + 2$, where m is the number of nodes traversed, that is, twenty in the 20 msec., so the potential number of neurones is 762. With a multi-dimensional network the number of neurones, N, is given, when m is large relative to n, by the general formula, $N \sim \frac{2^n}{n!}\, m^n$, which for $m = 20$ (that is, 20 msec.) and for $n = 4$ (that is, each neurone the receiver and giver of four effective synaptic contacts) gives a total of the order 10^5 neurones involved in 20 msec., and for $n = 5$ the total is of the order 8×10^5. These calculations are intended merely to give some indication of the large number of cortical neurones that could be affected by a discharge originating in any one. When a high level of activity prevails in the cerebral cortex, it may be conservatively estimated that, out of the hundred or more synaptic contacts made by any one neurone, at least four or five are effective in evoking the discharge of neurones next in series. The remainder would be ineffective because the respective neurones would not be poised at this critical level of excitability. So long as the assumed number of effective connexions for each neurone is kept at such values, it is probable that the conventions of the network structure give an approximate method of allowing for all the mass of feed-back connexions that occur in the closed chain linkages of the cerebral cortex[16,17]. Since the cortex is approximately 3 mm. thick and the mean density of neurones 40,000 per sq. mm. of surface[24], the spread to some hundreds of thousands of neurones can be treated as spreading indefinitely in all directions without restriction by the sheet-like structure of the cortex.

An alternative method of calculation may be based on the experimentally observed rate at which a wave of excitation spreads radially through the cortical network from an artificially stimulated focus[9,10,22]. The all-or-nothing character of the spread indicates that during the invasion almost all the neurones are being excited to discharge impulses. Basing the calculation on the value of 50,000 neurones per sq. mm. (the average for gyri[24]), an initially excited focus of 1 mm. radius would include about 150,000 neurones, and at the observed radial rate of spread of 20 cm. per sec. there would be a total invasion of about 4×10^6 neurones in 20 msec. The invasion of each neurone is attributable to the converging excitatory impulses that impinge on it and cause it to discharge. By means of the many synaptic terminals of its axon each of the initially excited neurones thus contributes to the invasion of many neurones and each of these in turn to many more, and so on for the twenty or so successive neurone discharges that occur along an outward spreading chain in 20 msec. Again we have the indication that an impulse discharged by any one neurone has in 20 msec. contributed directly and indirectly to the excitation of hundreds of thousands of neurones.

Thus, within 20 msec. the pattern of discharge of even hundreds of thousands of neurones would be modified as a result of an 'influence' that initially caused the discharge of merely one neurone. But further, if we assume that this 'influence' is exerted not only at one node of the active network, but also over the whole field of nodes in some sort of spatio-temporal patterning, then it will be evident that potentially the network is capable of integrating the whole aggregate of 'influences' to cause modification of its patterned activity that otherwise would be determined by the pattern of afferent input and its own inherent structural and functional properties. Such integration would occur over hundreds of thousands of nodes in a few milliseconds, the effects exerted on any and every node being correlated in the resultant patterned activity of the surrounding hundreds of thousands of neurones. Thus, in general the spatio-temporal pattern of activity would be determined by three factors: (1) the micro-structure of the neural net and its functional properties; (2) the afferent input; (3) the postulated 'field of extraneous influence'. It can be claimed that no physical instrument would bear comparison with the postulated performance of the active cerebral cortex as a detector of minute 'fields of influence' spread over a microscopic pattern and with temporal sequences of milliseconds. The integration, within a few milliseconds, of 'influences' picked up at hundreds of thousands of nodes would be unique, particularly when it is remembered that the integration is no mere addition, but is exerted to modify in some specific way "a shifting harmony of sub-patterns" of neuronal activity, achieving expression through the modifications so produced.

Thus, the hypothesis is that mind achieves liaison with the brain by exerting spatio-temporal 'fields of influence' that become effective through this unique detector function of the active cerebral cortex.

When the cortex is at a low level of activity, it would function inefficiently as a detector on account of the small proportion of neurones poised at the critical level of excitation and the consequent improbability of an effectively spreading influence; hence an explanation is provided for the invariably observed failure of mind–brain liaison when the electroencephalogram reveals depressed cortical activity. An explanation is also provided for the loss of consciousness in the stereotyped and driven cortical rhythms that occur in convulsions, for the nodes of the cortical network would also then lack the critical poise as well as the specific patterning. It is further to be noted that according to the hypothesis only a part of the cortex is needed for liaison with mind. It may be that any area that is in the critically excited state will do. This corresponds to the clinical evidence that mind–brain liaison is not interrupted by excision of a large part of the cerebral cortex, or when a large part is occupied by activity that excludes liaison, for example, by a convulsion or even by alpha wave activity[4]. Maybe less than a tenth of the neurones in the right state of activity is enough to give an effective mind–brain liaison.

When considering the manner in which mind could operate on matter, Eddington[4] discussed two hypotheses. In the first, it was postulated that mind could control the behaviour of matter within the limits imposed by Heisenberg's Principle of Uncertainty. Eddington rejected this partly because the permitted range would be exceedingly small. Presumably he was thinking of an object as large as a neurone. However, a neurophysiologist would consider the much smaller synaptic knob as the key structure on which a 'mind influence' might work. The synaptic knob is approximately a sphere 1·3 μ in diameter[12] and so would have a mass of 10^{-12} gm. If, as Eddington implies, the uncertainty principle is applicable to an object of this size, then it may be calculated that there is an uncertainty in the position of such an object of about 1·5 mμ in 1 sec. and 0·2 mμ in 20 msec. Such distances are very small; but it is conceivable that the excitatory efficacy of a synaptic knob would be appreciably affected by an uncertainty of this order, for the distance between the knob and the subjacent membrane is probably less than 100 mμ, and the excitatory efficacy would be expected to be very sensitive to changes in this value, at any rate on the electrical hypothesis of synaptic transmission[13]. Furthermore, as shown above, minute 'influences' thus exerted on a large population of neurones would be rapidly integrated in the form of a changed spatio-temporal pattern of activity in the neural net. There is thus in the active cortex a mechanism that could effectively amplify by thousands of times minute effects exerted on the individual synaptic knobs. It is therefore possible that the permitted range of behaviour of a synaptic knob may be adequate to allow for the effective operation of the postulated 'mind influences' on the active cerebral cortex. However, Eddington rejected this hypothesis for the further reason that it involved a fundamental inconsistency. First, behaviour according to chance was postulated in making a calculation of the permitted limits according to the uncertainty principle, then it was restricted by a non-chance or volitional action (the mind influence), which necessarily must be introduced if mind is to be able to take advantage of the latitude allowed by the uncertainty. Hence, Eddington was led to an alternative hypothesis of a correlated behaviour of the individual particles of matter, which he assumed to occur for matter in liaison with mind. The behaviour of such matter would stand in sharp contrast to the uncorrelated or random behaviour of particles that is postulated in physics, and may be "regarded by us as something 'outside physics' "[4]. Either of Eddington's hypotheses could form the physical basis of the neurophysiological hypothesis that has here been developed for mind–brain liaison. This latter hypothesis has the merits of relating the occasions when the mind can operate on the brain to the observed cortical events during consciousness, and of showing how an effective action could be secured by a spatio-temporal pattern of minute 'influences'.

In brain–mind liaison the traffic is both ways, from brain to mind no less than from mind to brain. Existing knowledge of the brain provided the basis for the above hypothesis relating to the operation of the mind on the brain. The reverse traffic—brain action to mind—is still more perplexing; but, presumably, if the mind can operate on dynamic spatio-temporal patterns of activity in the cortex, it would be expected to be susceptible to operation in the reverse sense. That would be the operational path in all perception and in the memory of events.

It will be sufficiently evident that the hypothesis here developed is of a fragmentary and tentative character, but it is hoped that it may be of value in further theoretical developments on mind–brain liaison. An outstanding problem for consideration would concern the postulated action of the mind in a spatio-temporal pattern, for presumably it must so act if it is to cause significant modification in patterned activity of the cortex. However, that problem would appear less formidable if there were a sufficiently rapid and detailed feed-back from brain action to mind, which in any case must be assumed for perception.

It will be objected that the essence of the hypothesis is that mind produces changes in the matter-energy system of the brain and hence must be itself in that system. But such a deduction is merely based on the present hypotheses of physics. If these 'mind influences' were of a nature that precluded their detection by any existing physical instrument, then physicists would be ignorant of them, and the hypotheses of physics would necessarily neglect them. It is at least claimed that the active cerebral cortex could be a detector of such 'influences' if they existed. But there are also now extensive reports of well-controlled experiments that give evidence of a quite different kind that there is a two-way traffic between mind and the matter–energy system. Of particular significance for the above hypothesis of mind influence on brain are the psycho-kinetic experiments[25]. These experiments as described leave little room for doubt that very slight changes can be produced by some minds on moving physical objects such as dice, effects which are revealed only when statistical analysis is applied to relatively long series of trials. In particular, the striking decline in effectiveness with time would seem to exclude all physical factors. There are, too, the even better authenticated experiments of the complementary process called extra-sensory perception[26,27]. If these experiments are revealing facts, there is an interaction of physical events with mind, as indeed is also indicated above by Eddington's second hypothesis. If as men of science we reject these experiments, it should be done on the basis of established errors in their execution or interpretation. Such errors have evaded years of careful scrutiny by unsympathetic critics. It will be agreed with Rhine[26] that, if the so-called psi-capacities (psycho-kinesis and extra-sensory perception) exist, they provide evidence of slight and irregular effects which are precisely of the nature that must be postulated for brain–mind liaison, but which occur there in highly developed form. The present hypothesis would offer an explanation for this high development of matter–mind traffic in the active human cerebral cortex, the development including not only continuous operation but also exquisite subtlety in transmission. Both these features would receive explanation on the basis of the interlocking, integrating and ever-changing pattern of activity formed by the multiple (ten thousand million-fold) detectors that exist in the cortex during consciousness.

THE WEST AUSTRALIAN FLORA*

By Sir EDWARD SALISBURY, C.B.E., F.R.S.

IN order to appreciate the character of the Australian flora it is necessary to realize first of all the influence of the extent of this vast continent isolated by large stretches of ocean from the nearest land mass. The localized distribution in Australia of large centres of population is a sufficient indication of the markedly peripheral distribution of situations favourable to human activity. Indeed, it is true that only about 15 per cent of the total of nearly three million square miles, which is approximately the area of Australia, has a rainfall of more than thirty inches, and this has to be considered in relation to the high and sometimes very excessive summer temperature. Furthermore, the average rainfall data in Australia are perhaps even more misleading than most averages, for nearly half Australia has a rainfall variability of 40–50 per cent, and even in the more habitable parts a variability of 20 per cent is by no means infrequent. In other words, the greater part of Australia is arid for a shorter or lengthier period, and the more arid region, abutting as it does upon the north of the Great Bight which reaches to the Nullabor Plain, means that Western Australia is isolated on the east by thousands of miles of desert as effectively as it is on the west by thousands of miles of ocean. Thus Western Australia is only capable of supporting in its central region specialized vegetation of an extreme xerophyllous type. Western Australia is, in fact, almost isolated from all the most favourable areas for vegetable growth except for its own south-west corner, where temperate rain-forest occurs.

A further point of some importance is that many of the soils in the southern and central parts are comparatively recent. In common with the most favourable areas for vegetation, the geologically ancient areas are likewise marginal. It is therefore scarcely surprising, when we consider all these facts together, that we find the flora of Western Australia is as a whole, like other isolated areas of far smaller extent, characterized by the high proportion of endemics which it comprises, amounting to about 85 per cent of the total.

Nevertheless, despite the isolation of Australia as a whole and of Western Australia in particular, the flora shows affinities with those of South America and South Africa. The facile explanation that some authorities have favoured that the former Antarctic Continent provided land connexions for the migration of a common flora between Australia, South America and South Africa would appear to be an anachronism of wishful thinking, since there is no evidence that the flowering plants, as we understand that group to-day, were differentiated until long after such land connexions had ceased to exist, and indeed the extensive Cretaceous transgression of the ocean that rendered the separation of these areas probably much greater than to-day occurred about the time that the Angiosperms perhaps evolved.

One family, rich in endemics, that is especially a feature of Western Australia, is the Myrtaceae. Members of this family have a wide distribution in warm regions, but the genus *Eucalyptus* with some three hundred species is almost confined to Australia with many species only found in the west, and one of the most beautiful of these endemics is *Eucalyptus macrocarpa*, with large red flowers. Other striking members endemic to Western Australia are the Geraldtown wax flower (*Chamælaucium*), and above all the beautiful fringe flowers (*Verticordia*) which adorn with their dainty blossoms the arid sandy heaths of the West where more than three-quarters of the forty known species are alone to be found. They owe their name to the fringe-like sepals, and in some species the petals are dissected also. The genus *Calothamnus* comprising twenty-five species is entirely Western Australian, and all these exhibit leaves highly resistant to desiccation.

---

* Substance of a Friday evening discourse delivered at the Royal Institution on May 18.

The Proteaceæ is one of the most characteristic families of the Australian flora, and this group would appear to have had a wide distribution in Tertiary times. Although many of the so-called proteaceous fossil leaves are of dubious attribution, there seems little doubt that the family was formerly represented in the northern hemisphere, as the late Sir Albert Seward, after a critical assessment of the evidence, concluded. Moreover, recent studies in Australia have shown that the family even there had a more extensive distribution than to-day. The present geographical range is wide over the southern hemisphere but discontinuous, with concentrations in South Africa and Australia; but by far the largest number of endemic species are located in Western Australia. It is therefore difficult to escape the conclusion that this is an ancient family that has experienced a diminishing range and increasing differentiation through the past thirty million years of its history. It is a specialist family peculiarly fitted for growth in conditions of great seasonal aridity and correspondingly unfitted for competition with the more vigorous and faster growing types in conditions more favourable to plant growth. Thus the increasing restriction of this family is probably to be attributed to ecological causes: the climatic differentiation of recent epochs which, combined with soil development, have produced localized areas that constitute the sanctuaries for its survival.

Of the total of fifty genera in this family it is true that only five are confined to Western Australia, the most important being the genus *Dryandra*, with some fifty members, but altogether more than 370 species of Proteaceæ, or almost two-fifths of the entire family, are restricted to this area.

The foliage of the Western Australian proteaceous trees and shrubs is uniformly leathery in texture, but may be needle-like and unbranched as in some species of *Hakea*, or broad and flat as the leaves of *Banksia menziesii*; but, in all, the foliage shows but little change when dried. This is due to the rigid interior skeleton and robust epidermis, which offer a great mechanical resistance to desiccation. The surface is covered with a thick cuticle almost impervious to water vapour, and the stomata are usually sunk in pits and often protected by perforated domes of cuticle which diminish the effect of hot, dry winds. It is noteworthy that a branch of *Dryandra* that has been detached from the plant for more than a year retains the form of its leaves almost unaltered, thus bearing witness to the mechanical resistance to shrinkage and so to loss of water vapour.

It is this same adaptation to drought conditions that is doubtless responsible for the striking similarity of growth habit which is often exhibited by species of different genera and families. I was much impressed by this feature in a heath-like area of scrub towards the edge of the Nullabor Plain, where the average rainfall was between 10 and 15 in. per annum. Here members of a number of families showed a marked similarity of vegetative structure sometimes so close as to render them almost indistinguishable, except by the expert, when not in flower. Such epharmony is particularly well exemplified by the ericoid habit, not only shown as we should expect by the Epacridaceæ but also by *Hibbertia hypericoides* (Dilleniaceæ), *Leschenaultia formosa* (Goodeniaceæ), *Boronia megastigma* and *Thryptomene* sp. (Myrtaceæ), *Acacia rossii* (Leguminosæ), *Eremophila* (Myoporaceæ), *Petrophila ericifolia* (Proteaceæ), and even by the Liliaceæ in that remarkable shrub *Calectasia cyanea*, to mention but one representative from seven different families; but this list could be extended almost *ad nauseam*.

Again, the switch-like habit in which the leaves have undergone extreme reduction is paralleled in a number of quite unrelated species. Examples are furnished by the phyllodic species of *Acacia*, where the function of the leaves is assumed by green modified leaf stalks or flattened stems; and by the she oaks (*Casuarina*), looking like woody horsetails with minute leaves on green longitudinally grooved stems, these grooves providing shelter for the stomata, which are further protected by the presence of hairs. The Restionaceæ is a particularly characteristic Australian family, where the stems also perform the function of leaves.

Alike in these plants the assumption of the leaf function by stem or leaf-stalk has resulted in an increase of mechanical resistance to water-loss and thus in a prolongation of photosynthetic activity.

The shelter afforded by a felt-like covering of woolly hairs which protects the surface of the plant from direct wind action is well exemplified in the Verbenaceous genus *Lachnostachys*, aptly known by the popular name of lamb's tails. Here the white appearance, which the air-filled hairs confer, bears witness to the large amount of the incident light which is reflected and thus enhances the protection that the hairs afford. As a second example mention may be made of the flannel flowers (*Actinotus* sp.), which belong to the Umbelliferæ and recall the edelweiss of the European flora.

The succulent habit is not commonly represented except in the saline areas, where perennial members of the Chenopodiaceæ such as *Salicornia australis* are frequent and exhibit this feature, as also annual species of *Zygophyllum*.

The extreme habitat conditions call forth a similar adaptation for resistance to water loss in such an unlikely group as the Liliaceæ. The Western Australian representatives of this family includes two arboreal genera, namely, the blackboys, *Xanthorrhœa*, and the grass tree, *Kingia australis*. These both have long grass-like leaves internally supported by sclerotic tissue. In the triangular or quadrangular leaves of the blackboys there is a thick investment of woody tissue just beneath the surface that resists shrinkage. In *Kingia* there are in addition internal woody bands that augment the resistance to shrinkage and thus to the escape of water vapour. It should perhaps be emphasized, what is too often overlooked, that the so-called transpiration checks are mainly of importance as prolonging the period of photosynthetic activity and thus fulfil their purpose, even if the leaf eventually wilts or even dies. In order to emphasize that death may not result from extreme desiccation my own experience with *Kochia tomentosa*, one of the Western Australian salt-bushes, is worth recording. I gathered a piece of this plant and, being uncertain of its identity, retained a small sprig and placed this in my pocket-book, where it remained in a very dry and brittle condition for three weeks while I was travelling by a roundabout route to Adelaide via Melbourne and the Murray Valley. It was then packed up with some papers and dispatched to England, where it remained in a centrally heated room for some months. Then taken out, it was inadvertently placed on the top of a cupboard in an unheated room during a spell of foggy weather. When found a week later it had put out some small shoots of diminutive new leaves. What osmotic suction it had attained I hesitate to guess.

The so called protocorm of that unique Australian lycopod, *Phylloglossum drummondii*, to which such importance was attached during the phylogeny hunting of the early years of this century is probably only biologically significant as presenting another adaptation to an intermittently arid environment that we see so strikingly developed in the tuberous sundews. British sundews, which grow in permanently damp places, have a meagre root system, but these Australian sundews, which grow in areas that are under water in winter but become dry and arid sandy wastes in summer, seem invariably to possess an underground tuber two to six inches beneath the surface according to the species. From such a hard round tuber arise the long stems of the climbing species that deck the branches with their glistening leaves and bear at the summit large white, pink or even yellow flowers. The sundews are particularly well represented and very diverse in character. *Drosera macrophylla* has a rosette of large leaves which together with the white flowers arise from a black tuber about half an inch in diameter and four or five inches deep. Some are like our own species, while *Drosera gigantea* suggests a sea lavender with numerous small white flowers on a richly branched inflorescence that arises from a deeply seated black tuber of elongated form. This tuberous habit can be regarded as a means of evasion of the climatic extremes, and can hence be compared with the annual habit so well exemplified by the ephemeral Compositae of the desert areas that compass their whole life-history in a few weeks after the infrequent rains. These composites paint the desert like a Joseph's coat of many colours, and not the least interesting feature is the marked dominance of one species over a considerable area, so that you may get square miles looking white with the presence of *Helipterum niveum*, while farther on are acres which are yellow or red through the dominance of other species. What the factors are which determine this dominance is uncertain. Very often there is no obvious soil difference to account for this. Like most desert annuals, the Australian species are short-lived plants which germinate during appreciable rain and pass their whole life-history within a few weeks. If, as may well happen, no appreciable rain falls, the seeds remain dormant until conditions become more suitable; but the abundance of these annuals bears witness to the relative fertility of the soil and to the limiting conditions upon vegetation which are imposed by the vagaries of the climate.

The sandy coastal plains are chiefly characterized by their poor soils, consisting of alluvial deposits so notoriously deficient in nutrient salts as to produce herbage inadequate for the support of healthy sheep and stock and responsible for the coastal diseases. We now know that these are the outcome of deficiencies, especially in the trace elements copper, zinc and cobalt. The last, though only requisite in amounts measured in parts per ten million of the food eaten, is now known to be essential to the well-being of ruminants, while zinc and copper are, in amounts of similar diminitude, essential alike to plant growth and animal welfare. The spraying of spruce trees with very dilute solutions of zinc sulphate has a most spectacular effect on the rate of growth of this tree on these soils. This response is indicative of the influence that such deficiencies may exert on competition on one hand between species that are tolerant of meagre rations of these trace elements or particularly efficient in their appropriation from inadequate supplies, and, on the other, those species that make greater demands for such upon the soil or are perhaps less efficient in their exploitation.

Not the least interesting feature of the Australian flora is the way in which species after species introduced from the Mediterranean or South Africa has 'run amok' in those areas where man has disturbed the natural vegetation.

It is possibly true in Australia, as the late Dr. Cockayne said of New Zealand, that the native species are quite capable of holding their own against introductions except where man disturbs the natural conditions. The native species are, in fact, specialists, peculiarly fitted to the natural environment. But certain it is that in the areas occupied by man or materially disturbed by him the introductions have established themselves in Australia in a most spectacular way. Near Humbug Scrub, not far from Adelaide, one can see many acres of pasture almost completely occupied by the globe artichoke, which, beautiful though they are in flower, are apparently of little value. Again, the Mediterranean bugle, *Echium plantagineum*, has been encouraged in some of the arid areas as providing fodder during the dry season, and here it rejoices in the name of "Salvation Jane"; but one sees potentially good pastures ruined by its superabundance in the region of Port Augustus, and here it is called "Patterson's Curse"! The many acres which it there covers with its blue flowers are to the mere visitor a charming sight. Again, the South African *Oxalis cernua* was introduced into Australia as a garden plant and was at one time sold at *4s. 6d.* a root. To-day one can see citrus orchards in which the whole of the ground among the citrus trees is one continual sheet of yellow with its brilliant flowers, and soursop, as it is called, has likewise become a pest in many parts. To-day, too, one can see in southern Western Australia the arum lily (*Richardia*) occupying the ditches, and tall species of *Watsonia*, constituting what might almost be described as thickets, and species of *Homeria* rendering poisonous the pastures they infest. It is no wonder that Australians to-day hesitate to grow even the most beautiful of the South African plants for fear they should get out of hand and become one more pest added to the unwelcome invaders. One has only to see the swamps in Western Australia invaded by arum lilies or the exuberant species of *Watsonia* to realize how easily erstwhile garden plants can become a curse.

If we consider the flora of West Australia in its wider aspects we cannot but be struck by the fact that it is at once highly specialized, but small and restricted in character in relation to the area involved. Despite its million square miles the total vascular flora numbers only about 5,800 species. It is true that much of Western Australia is desert; but a large part of this carries its own specialized flora. To apprehend the relative paucity it is sufficient to state that the whole of France with scarcely one-fifth of the area of Western Australia has a flora containing nearly five thousand species or roughly five-sixths, and comprising a far greater diversity of genera. The flora of France comprises more than 884 genera compared with only about 560 genera in the flora of Western Australia. Still more significant is that South Africa, with a similar area to Western Australia, has more than twice the number of genera. Isolation has thus on one hand permitted a high degree of specialization; but this has progressed in a much less varied biological community than would obtain in an area that had not been isolated and may well account in large measure for the vulnerability of the Western Australian flora to competition from immigrants when conditions of their environment are changed.

NEWS and VIEWS

Physics at Queen's University, Kingston, Ontario: Prof. J. K. Robertson

After forty years of faithful and constructive service, Prof. John Kellock Robertson, head of the Department of Physics at Queen's University, Kingston, Ontario, has resigned. Prof. Robertson was born in Perth, Ontario, in 1885. He attended the local schools and entered the University of Toronto, where he graduated in 1907, and later served as demonstrator in the Department of Physics. He was appointed lecturer in physics at Queen's University in 1909, and except for two years when he was absent at Cambridge during 1912–13 and at the Imperial College of Science and Technology, London, as visiting professor during 1933–34, he has worked there ever since, becoming head of the Department in 1943. He received the degree of doctor of laws at the spring convocation this year at Queen's. For many years he was a member of the Faculties of Arts, Engineering and Medicine—something almost unique in Queen's administration. His lectures on optics were well known, but he achieved the greatest distinction in his courses for medical students. He was elected a Fellow of the Royal Society of Canada in 1926, served as secretary of Section III for several years and was elected president of that Section in 1942–43; finally, in 1944, he was elected president of the Society.

During his long career, Prof. Robertson has found time to write many papers and books. Among the books should be mentioned a volume on physical optics which appeared in 1929 and has gone through three editions. This is an exceptionally readable and comprehensive text and is a very useful introduction to the subject. His book on X-rays and X-ray equipment is designed primarily for medical students and practitioners. Of a less formal character is a charming little book entitled "Atomic Artillery", the title of which tells its scope. His research interest, as shown by numerous papers, has been in the field of discharges in gases and vapours excited by high-frequency and micro-waves. For many years he served on the editorial board of *Queen's Quarterly* and has contributed articles to this and other journals. Prof. Robertson will be remembered by many graduates as an enthusiastic and inspiring teacher. Those who were fortunate enough to work with him in his own laboratory have been profoundly impressed and form a group of progressive and resourceful young physicists. In his retirement he has left Canada to live with his daughter, who has resided in London for a number of years.

Prof. B. W. Sargent, M.B.E.

Dr. B. W. Sargent, who is succeeding Prof. J. K. Robertson, leaves the post of assistant director of the Physics Subdivision, Atomic Energy Project, Chalk River, Ontario. Born at Williamsburg, Ontario, in 1906, Dr. Sargent received his early education in local schools and at Queen's University, where he obtained his B.A. in 1926 and M.A. in 1927. Following graduation, he spent two years at Queen's doing research in radioactivity under the direction of Prof. J. A. Gray, Chown research professor. The award of an 1851 Exhibition Scholarship in 1928 enabled him to spend the next two years at Cambridge, where he continued research in radioactivity at the Cavendish Laboratory under Lord Rutherford. His work there on beta-ray spectra and related problems led to an important relation known as Sargent's Law. In 1930 he returned to Canada as a lecturer in physics at his *alma mater*. For the next thirteen years he combined teaching duties with research so successfully that in 1941 he was elected a Fellow of the Royal Society of Canada. In 1943 he was granted leave of absence to join the Atomic Energy Project, Montreal Laboratory, under the National Research Council of Canada. Resigning from the staff of Queen's University in 1946, he has remained with this group until the present time; during 1945–50 he was head of the Nuclear Physics Branch, first at Montreal, then at Chalk River, and since January 1, 1951, he has been assistant director of the Physics Subdivision there. Dr. Sargent is an authority on problems relating to neutrons and to heavy-water piles, and has published papers on these and other subjects.

U.S. Navy Aviation Medical Acceleration Laboratory: Prof. Robert F. Rushmer

The University of Pennsylvania and the U.S. Naval Air Development Center at Johnsville, Bucks County, Pa., have announced the appointment of Dr. Robert F. Rushmer, of the University of Washington, Seattle, Washington, to be superintendent of the Scientific Department at the new Aviation Medical Acceleration Laboratory of the U.S. Navy. This Laboratory is one of the five laboratories of the Naval Air Development Center, which has made an agreement with the University of Pennsylvania whereby there is to be mutual exchange of personnel and facilities between the two institutions. Dr. Rushmer has also been appointed professor of applied physiology in the Faculty of Medicine, University of Pennsylvania; others appointed to the Aviation Medical Acceleration Laboratory will also receive appropriate faculty appointments in the University. The new Laboratory is at Johnsville, approximately eighteen miles north-east of Philadelphia, and its main functions will be the study by naval and civilian medical authorities of man's reactions to acceleration under conditions closely resembling the stress patterns encountered in actual air combat. The Laboratory has been designed as a complete aero-medical laboratory, well equipped for work in physiology, animal surgery, radioactivity, biophysics, biochemistry, gas analysis, pathology and electronics, a medical library, conference rooms, service and fabrication shops.

Dr. Rushmer is a native of Ogden, Utah, where he was born in 1914. He graduated from the University of Chicago in 1935 with a science degree and from Rush Medical College in 1939 with a medical degree. During 1940–42 he studied at the Mayo Clinic, Rochester, Minnesota, with a fellowship in pediatrics. In 1941 Dr. Rushmer was appointed an assistant in aviation medicine at the Mayo Foundation, and he served as a research projects officer in the Department of Clinical Investigation, AAF School of Aviation at Randolph Field, Texas, during 1942–46 inclusive. After the War, Dr. Rushmer joined the medical faculty of the University of Southern California as an associate professor of aviation medicine, and in 1947 he took up a similar appointment in the University of Washington.

Royal Society of Edinburgh : Honorary Fellows

At a meeting of the Royal Society of Edinburgh held on July 2, the following were elected Honorary Fellows of the Society.

British : Sir Charles Harington, director of the National Institute for Medical Research ; Sir Harold Spencer Jones, Astronomer Royal.

Foreign : Prof. George W. Corner, director of the Department of Embryology, Carnegie Embryological Laboratory, Baltimore ; Prof. H. A. Kramers, director, Institute of Theoretical Physics, Leyden ; Prof. Vincent du Vigneaud, professor of biochemistry, Cornell University Medical School, New York ; Prof. Sewall Wright, professor of zoology, University of Chicago.

Prof. E. L. Hirst delivered the Bruce–Preller Lecture, his subject being "The Synthesis and Functions of Sugars in Plant Life". The Makdougall-Brisbane Prize (1948–50) was presented by the president to Prof. James Small, Queen's University, Belfast, for his papers dealing with quantitative evolution, two of which have been published in the *Proceedings* of the Society during the period of the award.

Development of Atomic Energy in Great Britain

In the House of Lords on July 5, Lord Cherwell put forward a motion regretting "the slow progress made in this country in developing atomic energy for peaceful and for war-like purposes", and asking for the transfer of the work from the Ministry of Supply to a special organization "under the direct control of the head of the Government". He remarked that the matter had become more urgent in view of the impending retirement of Lord Portal, director of atomic energy, whose chief scientific adviser had already left the service. The Civil Service, he said, is unfitted for dealing with this kind of undertaking ; and a more flexible organization is required. Many good engineers and scientific men are reluctant to join the Civil Service because their work would be regulated by the administrative side, which knows little about the subject. Lord Cherwell also referred to security measures, which he believes are inadequate as applied in this field. No other country, he said, has attempted to carry on research and development in atomic energy through a government department, and he asked for a change of organization as a matter of urgency.

The Government reply was by Viscount Alexander, chancellor of the Duchy of Lancaster. He remarked that the Government is quite prepared to change its views on this important matter if it is convinced that progress is being held up in any way. In point of fact, however, the Sellafield development, he said, has been completed well within the time schedule. Any new organization would be faced with the same shortages and frustrations due to post-war difficulties which have hampered not only the Civil Service but also every part of industry in Great Britain. Further, he believed that a change of organization at the present time would cause considerable disturbance and set back the atomic energy project by months. He claimed that under the Ministry of Supply there has been no delay in decisions on policy, no lack of money and, until recently, no difficulty in recruiting a proper share of the country's scientific men. The Prime Minister had given instructions that the project was to have the highest priority, and it has been conducted on the largest scale possible in view of the country's resources. The present arrangements, Lord Alexander said, do not preclude a close degree of personal attention by the Prime Minister. Lord Cherwell's motion was carried by 52 votes to 31.

British Coal Utilization Research Association : Annual General Meeting

The successful fusion in Great Britain of the research interests of the nationalized coal and electricity industries with those of the independent appliance manufacturers and coal consumers in an autonomous co-operative research association was referred to by Sir Charles Ellis during the course of his presidential address at the annual general meeting of the British Coal Utilization Research Association held on June 13 at Leatherhead. Introducing the annual report of the Association for 1950, Sir Charles, after commenting upon the success of the system of committees by which the affairs of the Association are conducted, and upon the satisfactory financial position, reviewed briefly a few of the more outstanding activities and achievements of the Association during the year. The investigation into the effect of coal characteristics upon the performance of shell boilers, for example, had provided quantitative data on the beneficial effect of using coal of the correct moisture content ; studies of the performance of gas producers had revealed a promising new method of automatic control based on an instrumental link between coal feed and off-take gas temperature ; a new study of the gasification of slurries had been commenced ; work was progressing on the design of a cyclone furnace which should provide not only a power source for a gas turbine, but also a method for the economical combustion of coal intermediate in size between normal boiler fuel and pulverized fuel ; and the work on domestic heating was being directed towards the achievement of smokeless combustion in open fires. Finally, Sir Charles Ellis announced the establishment of an annual Coal Science Lecture, believed to be the first ever inaugurated by a research association, and announced that Sir Alfred Egerton had been invited to be the first lecturer.

Regulations concerning Full-time Work in the Colonial Service

One of the constituent institutes of the Joint Council of Professional Scientists recently directed the Council's attention to the varying interpretations, in respect of men of science in the service of Colonial Governments, which are placed on paragraph 52 of Colonial Regulations (Colonial No. 88–1 of 1945), namely: "An officer whose remuneration is fixed on the assumption that his whole time is at the disposal of the Government is prohibited from engaging in trade, or employing himself in any commercial or agricultural undertaking". While agreeing that it is undesirable for servants of Colonial Governments to act as consultants to industrial firms, the Joint Council expressed the view to the Colonial Office that it was not in the best interests of the Service for this rule to be interpreted in such a way that it would prevent a scientific worker acting, for example, as a university examiner or undertaking other academic work or contributing to scientific literature in the ordinary way. The Council's view was that much would be gained if scientific members of the staff of an establishment were free to undertake such extra-mural work as the director of research, or other responsible officer, expressly approved, and if these directors and officers had wide discretion in authorizing such work and in deciding what extra-mural activities they themselves should undertake. These views were submitted to the Colonial Office in a document signed by its chairman and the presidents of its four constituent bodies: the Institute of Biology, the Royal Institute of Chemistry, the Institution of Metallurgists and the Institute of Physics.

The Assistant Under-Secretary of State for the Colonies in charge of research, both in interview and in correspondence, pointed out that it is a matter of common practice for scientific officers in the service of Colonial Governments to contribute to scientific literature, and in the same way other officers frequently publish matters not excluded by the terms of the Colonial Regulation. He also pointed out that it is by no means uncommon for specialist officers employed by a Colonial Government to undertake, for remuneration, lectures at a university or college in the territory and to serve as external examiners. The official view is that in general the regulations are interpreted reasonably from the point of view of both scientific and other officers and of the Colonial Governments; but the Secretary of State has undertaken to inquire into any particular case where it is considered that an unduly strict interpretation of the relevant Colonial regulations has been adopted.

Co-operation between the Cape and Radcliffe Observatories

All interested in astronomical observations will welcome the adoption of a scheme for co-operation between the British observatories in South Africa. By payment of an annual sum to the Radcliffe Trustees, the Cape Observatory will secure the use of the 74-in. reflector at Pretoria for a third of the observing time. As is well known, the funds available for the Radcliffe Observatory suffice for the employment of only three astronomers—not nearly enough to make full use of the telescope, which is the largest in the southern hemisphere. The additional sum made available will enable the Observatory to engage a mechanic-night assistant and a secretary-librarian, and so take a burden off the scientific staff. What money is left over will be used for improving the subsidiary equipment and buildings. At the same time, the Cape Observatory will be enabled to extend its researches; for although it has many instruments, they have only moderate light grasp and most of them are fifty or more years old. The Cape Observatory has no reflecting telescope. For the last few years the Cape astronomers have had occasional use of the 74-in. reflector through the courtesy of the Radcliffe Observer, and they can appreciate the possibilities of the new arrangement. Astronomers are only too well aware of the exasperating delays which almost always take place between the planning of a telescope and bringing it into use, and the fact that the 74-in. reflector is already in operation is a point of no small importance.

The Elliott Journal

In 1800 William Elliott set up in business as a maker of scientific apparatus, and for a hundred and fifty years the firm, now Elliott Brothers (London), Ltd., has been associated with instrument making. It is appropriate that the achievements of this firm, its history and the work it is doing should be made known as widely as possible. We therefore welcome the first number of *The Elliott Journal*, admittedly a house journal but one which will be read with interest by many not immediately associated with the firm. The *Journal* is to be published half-yearly and its aim is to give a periodical review of developments in engineering and physical science with particular reference to the work of Elliott Bros. The first number contains a brief foreword by Sir Ben Lockspeiser; a summary of the history of the firm since its foundation; and eight illustrated articles. These discuss the following topics: magnetic amplifiers and their application to industrial purposes; pulsed circuits for resistance strain-gauges; application of the force-balance principle to pneumatic instruments for process control; a photo-electric curve follower; precision A.C. measurement with a D.C./A.C. comparator; a phase-front plotter for testing micro-wave aerials; a precision sine–cosine potentiometer; and thermal fluctuation of charge in linear circuits.

Mycopathologia et Mycologia Applicata

The appearance of the first fascicule of Vol. 5 of the journal *Mycopathologia* under the enlarged title *Mycopathologia et Mycologia Applicata* indicates the wider range that has now been assumed by the journal with the inclusion of more general papers on applied mycology. As the former title suggests, *Mycopathologia* has for several years been the chief world repository for papers on medical mycology. The development of this subject must, indeed, have owed a good deal to the journal, for medical applications of mycology are now known in areas where human fungus diseases were largely unsuspected. Mycological pathology will, indeed, still be represented strongly. The present issue includes, *inter alia*, studies of antidotal properties of various fungi, against the staphylococcus toxin, by Anna Maria Villa; a detailed paper on vitamin deficiencies of pathogenic fungi, by A. E. de Arêa Leão and Amadeu Cury; a critical survey of mycological literature between 1939 and 1942 (Tibor Benedek); and a description of the fungistatic activities of vitamin K on dermatophytes, by A. E. Arêa Leão and Adolpho da Rocha Furtado. Typical of the wider scope is a paper on the enzymatic grouping of bacteria, by Costantino Gosini. *Mycopathologia et Mycologia Applicata* is published by Dr. W. Junk, of 13 Van Stolkweg, The Hague, Netherlands, and the present number is priced at 40 guilders, or £3 15*s*. 4*d*.

Research in the University of Birmingham

The Joint Standing Committee for Research of the University of Birmingham has issued in its twenty-first annual report a very convenient general survey of research completed and in progress during the academic year 1949–50. The departmental summaries are accompanied, as in the previous report, by particulars of theses approved for higher degrees and by lists of published work for the academic year 1949–50 which can be regarded as contributions to original knowledge. The whole presents a concise but impressive picture of the contribution coming from the University of Birmingham, and its value would be only enhanced if all universities followed this example. The increasing dependence of universities upon the State for financial assistance makes such reports a desirable, as well as a reasonable, complement to the reports coming from the University Grants Committee itself.

Personnel Management

In a recent issue of the *Journal of the Institute of Personnel Management* (33, No. 314; March–April 1951), the personnel officer in a large industrial organization puts forward constructive proposals why the 'closed shop' policy in industry should be accepted. In reply, other personnel officers suggest that to make membership of a trade union a condition of employment in any firm is an unwarrantable interference with the liberty of the individual. Among other articles in the *Journal* is one by Miss Helen Baker, the associate director of the industrial relations section at Princeton University, giving her views on joint consultative practice in British industry, a report on promotion policy in nationalized industries prepared by the Acton Society Trust, and an account of the training of new entrants for the Westminster Bank by L. C. P. Cann.

Penicillin Formation in Pea Juice

Popular interest in penicillin is matched by concentrated research to find more about the mechanism of its production. Dr. R. P. Cook and Dr. Margaret B. Brown have studied the production of penicillin on media containing juice of the pea (*Pisum sativum*) and compared it with that from media of known chemical composition (*Proc. Roy. Soc. Edinburgh*, B, 64, Part 2, No. 6; 1950). High yields of penicillin were obtained with one fraction of the pea juice, obtained by adding ethanol to the extract. The chemical composition of this fraction is complex; but the chief constituents have been determined. Other experiments with chemically defined media suggest that the highest yields of penicillin have been obtained only in the presence of a complex mixture of nitrogen-containing compounds. Excess of carbohydrates such as glucose caused an increase in growth but a rapid decrease in the production of penicillin. The Peoria strain 1249 *B*21 of *Penicillium notatum* was used in these experiments.

Correspondence of Lavoisier

Dr. Douglas McKie, University College, Gower Street, London, W.C.1, writes: "In 1948 the Academy of Sciences of Paris appointed a committee for the editing and publication of the correspondence of Antoine Lavoisier (1743–94), the great French chemist. A preliminary catalogue of all letters and documents so far traced in France was compiled by the secretary of the committee, Prof. René Fric, of the University of Clermont-Ferrand; and copies were distributed in 1949 to many libraries throughout the world with the request for further information, as a result of which many important items were located. As there may be others still untraced in Great Britain, I would be grateful to librarians and private owners for information of any such letters or documents in their care or possession."

Royal Statistical Society: Officers

At the annual general meeting of the Royal Statistical Society the following elections were announced: *President*, Prof. Bradford Hill; *Honorary Secretaries*, Mr. R. F. George, Mr. Richard Stone, Mr. Philip Lyle; *Honorary Treasurer*, Mr. R. F. Fowler. Mr. F. A. A. Menzler, president of the Institute of Actuaries, was awarded the Society's Guy Medal in silver.

Announcements

Prof. E. Guyénot, professor of zoology and comparative anatomy in the University of Geneva, has been elected a non-resident member of the Paris Academy of Sciences in succession to the late Prof. L. Cuénot.

Dr. Lillian M. Gilbreth, president of Gilbreth Incorporated and a member of the board of directors of the American Management Council, has been elected an honorary fellow of the British Institute of Management. This is the first occasion on which the Institute has made such an election.

'Open Days' at the Chemical Research Laboratory, Teddington (Department of Scientific and Industrial Research), have been arranged for September 19 (afternoon), September 20 (morning), September 21 (morning or afternoon). Applications to attend should reach the Director before August 31; firms already on the invitation list need not apply.

The forty-seventh Autumn Foray of the British Mycological Society will be held at Hereford during September 12–19, with headquarters at the Training College, Hereford, at which accommodation will be available. Those wishing to attend should notify the secretary, Dr. C. J. Hickman, Department of Botany, University, Birmingham 15, not later than August 11.

The Faraday Society, on the invitation of the National Research Council of Canada and various Canadian industries, will hold a general discussion meeting at the University of Toronto in September 1952. The subject will be "The Reactivity of Free Radicals". In addition, visits to various universities and industrial concerns are being planned. Those interested should communicate as soon as possible with the Secretary of the Faraday Society, 6 Gray's Inn Square, London, W.C.1.

A "Name Index of Organic Reactions", by Prof. T. S. Wheeler and J. E. Gowan, published by the Society of Chemical Industry (56 Victoria Street, London, S.W.1; pp. 46; 5*s*. net), gives briefly the nature of various reactions named after their discoverers, and should be useful to students of organic chemistry and others who may not recall what a particular reaction denotes. There are references to literature.

Erratum. In the communication "Vitamin B_{12} Content of Soft- and Hard-shell Clams" (*Nature*, July 7, p. 36), the organism mentioned in paragraph 3 is *Lactobacillus leichmannii*; in the last line of the same paragraph, for "0·4 μgm." read "0·5 mμgm.".

HISTORY OF SCIENCE AND TECHNOLOGY IN INDIA AND SOUTH-EAST ASIA

THE history of the sciences, pure and applied, in India and other parts of South Asia, still remains the greatest 'unknown continent' in this world of study, so important for the general cultural history of mankind. It was therefore an excellent idea to gather together in November 1950 a group of Indian and South Asian scholars interested in the history of science, and to publish, even if only in a provisional form[*], the papers which were read to the symposium. The result shows clearly that there is an enormous amount of material already available for the work of synthesis, in which we must attempt to place the development of science and scientific thought in India in its proper framework of parallel developments, some later, some earlier, in Europe and in other parts of Asia. It is also clear, however, from the papers in this symposium, that the task is perhaps the most difficult of all those which face historians of science to-day, owing to the extreme uncertainties in the dating of the most important texts, and even of actual objects which have survived.

Some of the papers, such as the general surveys given by A. S. Altekar and by R. C. Majumdar, are judicious and careful concerning this, and will no doubt be in greatest demand if copies are available separately. Some of the specialized papers (such as that by B. L. Raina) are also reasonably cautious. Unfortunately, this cannot be said of the majority of the papers, which put forward quite unacceptably early datings especially for texts purporting to date from the first two millennia B.C.; particularly bad examples are the two papers on astronomy (by Shukla and Dixit) as well as others on chemistry (by N. R. Dhar), embryology (R. V. Seshaiya) and medicine (G. V. Satyanarayanamurthi). The accompanying table shows the divergence of opinion. It is even maintained that the Babylonians owed the sexagesimal division of the circle and the system of twenty-eight lunar mansions to India. In general, we find throughout the papers too marked a chauvinistic tendency, an effort to minimize foreign influences on Indian science and to emphasize all outward transmissions—this is, of course, all too easy so long as Indian history has not been provided with a strict chronology. Typical of the desire to make a case is the praise bestowed upon the potters of the Mohenjodaro civilization (P. Ray), where no comparison is made with other pottery products studied by the author, nor is any ceramics expert cited whose opinion might carry weight. Along with these tendencies goes the fault of trying to read too much into ancient texts, as when the Pillar Edicts of Asoka or the text of the "Arthashastra" are appealed to as evidence for advanced fishery legislation (S. L. Hora); here the writer is roundly taken to task by a colleague (R. C. Majumdar). But great uncertainty seems to reign, for the sceptic himself seems to be perhaps too sceptical regarding the military use of arsenical smokes—which were certainly developed quite early by the Chinese. So while most of the writers are too rash, others are too modest, notably the writer on Siam (P. Rochanapuranandа), who disclaims any contribution of his own Thai people to science, failing to mention the work of la Loubère[*] in the seventeenth century, which shows that Europeans were at that time much interested in what the Siamese knew. Even if this turned out to be mostly Chinese—as it did—Siam must certainly have had something to show in fields such as textile technology. The same applies to the paper on Indonesian culture (Prijohutomo).

Until the problem of the dating of Indian texts is solved, all those of transmission must remain impossible to deal with. Hence the confidence shown by papers such as that on Indian–Chinese relations (P. C. Bagchi) is entirely misplaced. We cannot admit the derivation of the Chinese lunar mansions from India (probably both systems are ultimately Babylonian). It is absurd to claim Indian influence on a mathematical work such as the "Sun Tzu Suan Ching" (third century A.D.) on the ground that the word 'Ching' was afterwards used for translating the term 'Sutra' in Buddhist texts—all canonical books were known as 'Ching' from the time of the Warring States (fourth century B.C.). Nor is there any mention in this paper of the numerous cases which have been noted of the reappearance of Chinese mathematical problems in subsequent Indian texts.

Nevertheless, the study of the history of science in India remains enthralling. The following words of Filliozat, in the preface to his recent splendid monograph on the theories of classical Indian medicine[†], are well worth pondering:

"Some may doubt the legitimacy of placing Indian and Greek science on the same level, preferring to compare the former rather with that of Islam. The common opinion that Indian science lacked originality presupposes that it was derived from Greek science, and is therefore sister to the science of the Arabs. . . .

"This problem has been far too much prejudged. Indian scholars, moved by national pride, are prone to maintain that their sciences in high antiquity surpassed even those of to-day. In the West, on the other hand, many maintain that the spirit of scientific research could only have been born in Europe, and that what science the Indians had they borrowed. In either case the only proofs presented are a few examples claimed as characteristic and used as the basis for generalizations, hypotheses taking the place of facts which are still undiscovered or which people will not take the trouble to seek. Indeed, opinions rest on racial or national preconceptions rather than on a profound comparative study of the two great scientific traditions the value of which is to be determined. One notes also that those who speak with the greatest certainty in these matters are just those who are familiar with only one of the two traditions, knowing the other only by scattered facts, or studies which they are unable to appreciate. 'To say nothing, of course, of those 'authorities' who know nothing of either of the two traditions about which they speak.

"Charaka Samhita"	+1st (present text +8th)	−7th		−6th

"The greatest historians of science have not always escaped from the inconvenience of knowing only one side of the matter. Paul Tannery, so famous for his studies on ancient mathematics, is an example. We know that the trigonometric sine is not mentioned by Greek mathematicians and astronomers, that it was used in India from the Gupta period onwards (+3rd. century), that the *Surya Siddhanta* (+4th. or +5th. century) gives a table of sines, that the Arab astronomers knew them from their Indian contacts and passed them on to Europe in the +12th. century, when the work of al-Battani was translated into Latin. The only conclusion possible is that the use of sines was an Indian development and not a Greek one. But Tannery, persuaded that the Indians could not have made any mathematical inventions, preferred to assume that the sine was a Greek idea not adopted by Hipparchus, who gave only a table of chords. For Tannery, the fact that the Indians knew of sines was sufficient proof that they must have heard about them from the Greeks.

"If this is the way we are to argue, there was never any science other than Greek science, and the question whether science has any origins other than the Greek 'miracle' is solved in advance. Only a profound study of Indian scientific developments in parallel with those which took place elsewhere about the same times, can reveal the degree of originality of that science, and hence enable us to understand the rôle which India played in the history of the growth of man's knowledge of Nature."

In the present symposium, the writer on Siam ends, somewhat pathetically: "At present we all seem to believe that science is something which originated especially in Europe and the Near East, and that the Far East had no share in the building of this most important branch of human knowledge. Yet Asian countries such as India and China were important centres of culture both materially and spiritually. Their peoples had learned how to control the natural world around them, and to live a life in which there was room for leisure, only it seems that the knowledge gained by them never joined up with what we know today as modern science. However, Asian people now find no difficulty in learning science and do not lack ability in scientific research."

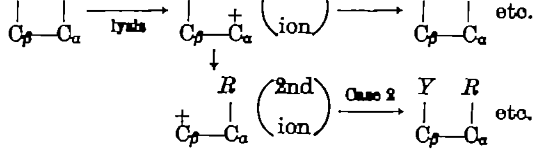
In my opinion, future research on the history of science and technology in Asia will, in fact, reveal that the achievements of these peoples contributed far more, in all pre-Renaissance periods, to the development of world science than has yet been realized. The programme of Filliozat is the answer to the perplexity of Rochanapurananda.

JOSEPH NEEDHAM

WAGNER CHANGES, SYNARTETIC ACCELERATION AND SYNARTETIC IONS

By F. BROWN, PROF. E. D. HUGHES, F.R.S.,
PROF. C. K. INGOLD, F.R.S., and J. F. SMITH
University College, London, W.C.1

IT has been established[1] that the Wagner rearrangement is a form of unimolecular nucleophilic substitution or elimination (S_N1, $E1$); its primary step is that of all such unimolecular reactions, namely, a heterolysis with the production of a carbonium ion. Let us, for present convenience, call the obvious structure for this ion that of the 'first' carbonium ion. This ion might simply take up an anion (S_N1 substitution), or lose a proton ($E1$ elimination). However, the characteristic phenomenon of a Wagner change is that, prior to any such occurrence, a carbon atom with its full octet shifts over from an adjoining position to the charge-centre of the first ion. If nothing else happened, this would produce what we might call the 'second' carbonium ion. It is from this that the rearranged products may be considered as derived, either by uptake of the originally separating anion (Wagner isomerization), or by uptake of a different anion (Wagner substitution), or by loss of a proton (Wagner elimination):



As shown earlier[2], some primary heterolyses are 'accelerated'; that is, they occur much more rapidly than when the bond undergoing fission has the same local surroundings in simpler molecules; some heterolyses are not accelerated. Also, some heterolyses involve Wagner rearrangements, and some do not. The relationship between incidence of acceleration and of the Wagner change requires analysis.

One possible mechanism for the acceleration of a primary heterolysis depends on the release, during the process, of initially stored non-bonding energy: this has been defined[2] as 'steric acceleration'. Obviously it might operate whether a Wagner change is involved or not. Another mechanism of acceleration, which could evidently operate when a Wagner rearrangement is involved, would gain the excess rate from a release of bonding energy during the bond-shift characteristic of the Wagner change: this we shall call 'synartetic acceleration', for a reason that will become clear later. We shall also note later, what is not immediately obvious, namely, that this mode of acceleration may operate even when a Wagner change is not involved. The ranges of incidence of the two accelerative mechanisms require consideration.

We have approached the two problems stated by trying experimentally to answer a number of simple guiding questions by the provision of examples. One might first ask: Can acceleration ever arise without a Wagner change? The following example shows that it can. The rate of hydrolysis of camphene-hydrochloride in aqueous solvents to camphene-hydrate and camphene is too great to be easily measured; it is obviously greater than the corresponding rate for simple tertiary alkyl chlorides. The rate of the analogous unimolecular ethyl-alcoholysis has been measured[3] (for example, $k_1 = 4{\cdot}0 \times 10^{-5}$ sec.$^{-1}$ at 0° in dry ethyl alcohol), and has been found to be about 6,000 times greater than the corresponding rate for *tert.*-butyl chloride.

The next question is complementary: Can a Wagner rearrangement ever occur without acceleration? Again the answer is affirmative. The unimolecular solvolysis of *neo*pentyl bromide[4], to give exclusively Wagner-rearranged *tert.*-amyl alcohol or *tert.*-amyl alkyl ethers and *iso*amylenes, takes place at rates ($k_1 = 1{\cdot}53 \times 10^{-6}$ sec.$^{-1}$, for hydrolysis at 95° in wet formic acid) which are of the same order of magnitude as those of the corresponding solvolytic reactions of ethyl bromide ($k_1 = 2{\cdot}70 \times 10^{-6}$ sec.$^{-1}$ in the same conditions). The unimolecular solvolysis of pinacolyl chloride, again to give exclusively Wagner-rearranged products, takes place at rates ($k_1 = 1{\cdot}94 \times 10^{-7}$ sec.$^{-1}$ in 80 per cent aqueous ethyl alcohol at 80°) which are of the same order as those estimated for the unimolecular solvolysis of *iso*propyl chloride ($k_1 \sim 5 \times 10^{-7}$ sec.$^{-1}$ in the same conditions)[5]. A similar comparison could be given of pinacolyl iodide and *iso*propyl iodide[6].

These two types of examples show that the boundaries of the areas of incidence of acceleration and of Wagner rearrangements intersect.

Next we ask: Can an accelerated Wagner change be shown to derive its rate from 'steric acceleration'? Theoretically, an affirmative answer is expected, because, given a sufficiently ramified structure, steric acceleration is a mechanism generally applicable to the primary heterolysis. However, an unambiguous example is difficult to provide. Probably the best available example is that of the isomerization of camphene-hydrochloride in aprotic solvents to *iso*bornyl chloride. It has been found[7] that chlorine exchange between camphene-hydrochloride and chloride ions takes place more rapidly than the isomerization, which is not catalysed by chloride ions; and the conclusion has been drawn[8] that the heterolysis essentially precedes the Wagner rearrangement, which occurs during one of two competing forms of ionic reassociation. Now the initial heterolysis is identical, apart from the solvent difference, with the initial stage of the solvolysis of camphene-hydrochloride, which, as noted above, is strongly accelerated, but involves no Wagner change. Hence the acceleration could be a 'steric acceleration'. But even here, as we shall see later, 'synartetic acceleration' is not excluded. However, having regard to the structure, and the large magnitude of the observed effect, we incline to the view that both mechanisms make substantial contributions.

The complementary question is: Can an accelerated Wagner change be shown to derive its rate from 'synartetic acceleration'? Here the answer is definitely affirmative. As indicated in an earlier communication[9], tritylmethyl chloride, like *neo*pentyl chloride, is incapable of easy bimolecular reactions; and hence its unimolecular reactions, which give exclusively Wagner-rearranged products, may be studied, not only in formic acid, but also in aqueous alcoholic solvents. Charlton, Dostrovsky and Hughes found[9] that in formic acid it was hydrolysed by water at a rate ($k_1 = 2{\cdot}3 \times 10^{-6}$ sec.$^{-1}$ at 95°) estimated as about 50,000 times that for *neo*pentyl chloride. Comparisons referring to aqueous alcoholic solvents gave similarly large ratios. We assume that steric acceleration could not apply to the ionization of a primary halide, and that therefore synartetic acceleration is here responsible.

The following example[3] is especially instructive. First, the unimolecular solvolysis of bornyl chloride, to yield Wagner-rearranged products of the camphene series, takes place at rates ($k_1 \sim 1{\cdot}5 \times 10^{-7}$ sec.$^{-1}$ extrapolated for 80°, in 80 per cent aqueous ethyl alcohol) which are of the same order as those of the solvolysis of pinacolyl chloride ($k_1 = 1{\cdot}94 \times 10^{-7}$ sec.$^{-1}$ in the same conditions). Secondly, the solvolysis of *iso*bornyl chloride, also to give rearranged products, has rates ($k_1 \sim 1{\cdot}4 \times 10^{-2}$ sec.$^{-1}$ as above) which are about 70,000 times those of pinacolyl chloride. Steric acceleration seems here to be excluded, because *iso*bornyl chloride, the *exo*-isomeride, can scarcely be supposed to have *more* non-bonding energy than bornyl chloride, the *endo*-compound: again we conclude that synartetic acceleration is responsible. Moreover, it neatly interprets the stereo-kinetic distinction. For in the *exo*-structure, a Wagner-type bond-shift could be initiated before the ionizing chlorine atom has attained the separation of the transition state of ionization (that is, before the chlorine atom has moved by more than about 0·4 A.); and therefore the initiation of the bond-shift could kinetically influence the heterolysis. But in the *endo*-structure, no such bond-shift could commence until the chlorine atom has passed out of the

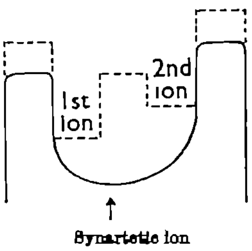


Fig. 1

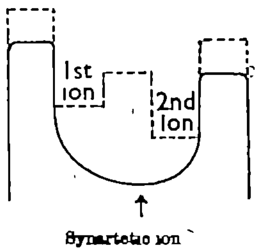

Fig. 2

(The reaction path enters from the left and leaves over whichever transition state lies lower, that is, by the left in Fig. 1 and by the right in Fig. 2)

Case 1, *sN* (broken line). Non-rearranging $S_N1/E1$ without synartetic acceleration (for example, solvolysis of *tert.*-amyl bromide).

Case 3, *sN* (full line). Synartetically accelerated non-rearranging $S_N1/E1$ (for example, solvolysis of camphene-hydrochloride).

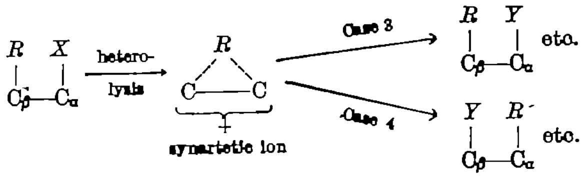
Case 2, *sW* (broken line). Wagner rearrangement, without synartetic acceleration (for example, solvolysis of *neo*pentyl bromide).

Case 4, *sW* (full line). Synartetically accelerated Wagner rearrangement (for example, solvolysis of *iso*bornyl chloride).

way (that is, to well beyond the transition-state distance); and thus the shift could here have no kinetic influence.

While recognizing that marginal situations arise, we can divide the reactions discussed into four main classes, as illustrated by the schematic energy-reaction curves of Figs. 1 and 2. In unaccelerated unimolecular reactions, whether or not they involve a Wagner rearrangement, the 'first ion', and the transition state of its formation, are unaffected by the existence, or possibility of existence, of the 'second ion'. We assume that in unaccelerated Wagner changes there must be two ions; but that when, in unaccelerated reactions, there are two, they are separated by an energy barrier substantial enough to preclude their energetically significant interaction. So we have either (case 1, *nN*) (the letters mean 'normal rate, normal structure') non-rearranging unimolecular reactions without synartetic acceleration (Fig. 1, broken line), or (case 2, *nW*) ('normal rate, Wagner change') Wagner rearrangements without such acceleration (Fig. 2, broken line), according as the transition state of the heterolysis which forms the 'first ion' lies energetically lower or higher than that of the co-ordination which destroys or would destroy the 'second ion'.

The other two classes can be most simply described by assuming that there is no resonance-stopping barrier between the first and second ionic structures, which interact according to a suggestion[10] made earlier, to produce a normal ion more stable than either—a *synartetic ion*, as we may call it, with a split single bond *fastening together* the locations of a split ionic charge. We then have not only a stabilized ion, but also stabilized transition states of ionization, and therefore either (case 3, *aN*) ('accelerated, normal structure') non-rearranging unimolecular reactions with synartetic acceleration (Fig. 1, full line), or (case 4, *aW*) ('accelerated, Wagner change') Wagner rearrangements with such acceleration (Fig. 2, full line), according, as before, to which of the two transition states lies lower. For these cases, we should modify our previous formulation:



Marginal cases (between 1 and 3, and between 2 and 4) should arise when a tunnel effect permits weak resonance between the first and second ions; but we shall not now discuss this phenomenon. Marginal cases of another sort (between 1 and 2, and between 3 and 4) arise when the two transition states lie on a common energy-level, so that the diagrams of Figs. 1 and 2 become symmetrical, as in Fig. 3. This happens when the unrearranged and Wagner-rearranged products are identical, but for some non-energetic distinction, as when they are enantiomeric, or are labelled isotopically. We then have either (border-case 12, *nNW*) reactions without synartetic accelerations (Fig. 3, broken line), or (border case 34, *aNW*) reactions with synartetic acceleration, leading, in either case, to 50 per cent of Wagner-rearranged product (for example, to racemization when the optical distinction is employed). A normal-rate reaction having the described symmetry (border case 12) has been found by Cram[11] in the solvolysis with racemization (at both asymmetric centres) of that form of 2-phenyl-3-*n*-butyl *p*-toluenesulphonate for which the normal and rearranged substitution products would be enantiomers.

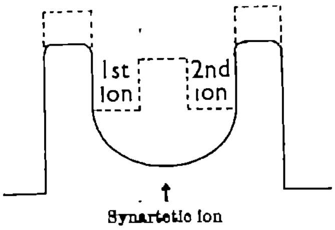


Fig. 3

(The reaction path enters from the left, then divides, and leaves equally by the left and by the right)
Border cases 1, 2 (broken line) and 3, 4 (full line)

One usually thinks of CC-bond σ-electrons as having a much smaller tendency to enter into other orbitals than have CH-bond σ-electrons, or of course π-bond-electrons or unshared *p*-electrons. Yet it appears that CC-bond σ-electrons can interact strongly with a carbonium ionic centre to form what we have called a synartetic ion, at least when the stereoelectronic situation is favourable, and when the normal types of conjugation and hyperconjugation are more or less restricted. This seems somewhat less strange when we recall that the carbonium ion has the same electron configuration as the tercovalent boron atom, and that it is one of the lessons of boron chemistry that all low-lying orbitals will somehow achieve partial occupation, even when there are too few electrons to occupy them fully (this was recently pointed out to us by Dr. S. H. Bauer): the same principle may apply in carbonium ion chemistry.

DIFFRACTION GRATINGS

THE Optical Group of the Physical Society held a symposium on diffraction gratings at the Imperial College of Science and Technology, London, on May 10. About seventy-six members and visitors attended and the meeting was generally very successful. A large number of exhibits and demonstrations illustrating the ruling and testing of gratings was shown.

Prof. W. E. Curtis, in introducing the subject, surveyed the present field of application of the grating and indicated the directions in which development is desirable. He mentioned a variety of problems in both atomic and molecular spectroscopy, for which gratings are required, in addition to spectrochemical investigations of a more routine nature, which are steadily increasing in number. He pointed out that for these various purposes a wide range of gratings would be required, particularly in regard to spacing and form of the rulings. He remarked, in passing, that it would be more appropriate to specify the spacing directly in microns, rather than as so many lines per inch, as hitherto. He also urged that the present custom of describing performance in terms of 'resolving power', $\lambda/\delta\lambda$, should be abandoned as neither physically significant nor practically convenient, and replaced by a statement of the limit of resolution (based on the Rayleigh criterion) in cm.$^{-1}$. This has the advantage of depending only on the ruled width of the grating and its setting, and not on the spacing or the spectral region. Its minimum value would be the reciprocal of twice the grating width, as in the reflecting echelon. The optimum spacing in a particular case would be determined by other considerations, such as the overlapping of neighbouring orders and the extent to which groove shape could be controlled.

Prof. Curtis then referred to some special modifications which may prove valuable in the future, notably the Harrison echelle grating. This has yet to prove itself, but certainly appears very promising. The combination of grating and mirror in Littrow fashion, as proposed by Hulthén and Lind, may well prove valuable in certain circumstances. He remarked also that the introduction of the photomultiplier renders a plane-grating – concave-mirror spectrograph an attractive proposition by reason of its simplicity of construction and adjustment.

So far as ordinary gratings are concerned, Prof. Curtis considers that there are four main directions in which improvement should be sought: the elimination of ghosts, either by perfecting the traditional ruling-method or by developing entirely new ones; the concentration of light in a given direction by control of groove form; the provision of larger gratings, although a greater ruled width only would suffice for some purposes; and finally, a substantial reduction in cost, so that a spectroscopist can acquire a number of gratings from which he may select the one best suited to each problem. Having regard to the effort already expended on the ruling of gratings, it might seem that only limited progress along these lines would be possible; but modern advances in technique and materials are such as to give good grounds for optimism.

Speaking of the history of the diffraction grating, J. S. Clark said that it originated in the pioneer work of Joseph Fraunhofer early in the nineteenth century. Reference was made to Nobert, of Barth in Germany (1850), and to Rutherford in the United States (1875), who was the first to rule a reflexion grating on speculum metal. The ruling of gratings at Johns Hopkins University, Baltimore, was initiated by Rowland in 1880 and continued by Anderson (1909), Wood (1923) and Strong. Other grating-ruling engines established in the United States were those of Michelson (1900) and Gale (University of Chicago) and those of Anderson (1916) and Babcock (Mount Wilson Observatory).

The Blythswood ruling engine, which has been in the possession of the National Physical Laboratory, Teddington, since 1908, dates from about 1880, when its construction was undertaken by Lord Blythswood with the assistance of Otto Hilger (one of the founders of the firm of Adam Hilger). Its subsequent history was described by Mr. Clark, and brief mention was also made of the ruling engines constructed by Grayson (1893) at Melbourne and by Siegbahn (1930) at Uppsala and at Stockholm. After pointing out that all existing ruling engines of conventional design have been either of the shaper type (for example, Rowland and Blythswood machines) or of the planer type (such as Strong's new machine at Johns Hopkins University), Mr. Clark went on to discuss the future prospects of ruling large gratings by conventional methods and concluded with a fairly detailed description of the Blythswood machine in its present state.

J. Guild described how interference tests, which have long been familiar in their application to the examination of mirrors, prisms, lenses and even complete optical instruments, can be applied to diffraction gratings, and stressed the fundamental importance of these tests in assessing the optical performance of gratings and indicating the nature, magnitude and location on the grating surface of the defects of figure or errors of ruling responsible for defects of performance.

The tests described were an adaptation of the well-known Fizeau test for plane mirrors to plane reflecting gratings: an adaptation of the differential interference (sheared wave-front) test developed by Ronchi and Bates for concave mirrors to either concave or plane gratings; and a test depending on the interference between the wave-fronts diffracted by a superposed pair of transparent replicas of a plane grating. For the second test Mr. Guild employed a simple beam-dividing device based on the Wollaston or Rochon double-image prism. This is free from some of the defects of Ronchi's apparatus and, while possessing all the flexibility required for the present purpose, is much simpler and less costly than the wave-front shearing interferometer of Bates. Slides were shown of interferograms obtained by each of these methods, those illustrating the first two being of gratings ruled on the Blythswood, Rowland and Siegbahn engines.

It was clear from those examples that, judged by ordinary optical standards, there is plenty of room for improvement in the best gratings produced by ruling engines of the traditional types. It was also apparent that the makers of gratings should be more careful than they seem to have been to rule only on blanks of good optical quality.

Dr. L. A. Sayce began by pointing out that diffraction gratings made by the traditional methods laid down by Rowland have certain defects, some inherent in all reciprocating engines and some attributable to the residual errors of screws, division plates, thrust bearings and the like. There is therefore special interest in a new approach to the problem suggested by Sir Thomas Merton which is being developed in the National Physical Laboratory by the Light and Metrology Divisions. Dr. Sayce explained that the fundamental concept is to rule diffraction gratings upon cylinders. Such helical gratings can be used directly in conjunction with cylindrical lenses or mirrors, but can more conveniently be used as matrices for the preparation of plane replicas of which many identical 'copies' can be made from each original ruling.

Using this principle, therefore, the production of a plane grating now consists of three main stages. In the first, a screw of up to 15,000 threads per inch is cut upon one-half of a metal cylinder using a suitably modified lathe. In the second, this lathe-cut thread is copied upon the other half of the cylinder using a 'Merton nut' to remove its inevitable periodic errors. In the third stage, the corrected helix is covered with a thin layer of plastic which, when hardened and annealed, is removed from the cylinder and opened out upon an optically flat surface of swollen gelatine. When the whole has dried, the plastic 'pellicle' can be removed, and the underlying gelatine is found to be moulded into a flat replica of the corrected helix and can be hardened and aluminized.

It was shown by means of specimens and interferograms that these methods have already produced satisfactory gratings, particularly for work in the infra-red, and there seems every reason to hope that they will in due course yield large ghost-free gratings suitable also for emission spectroscopy. As it has been found impossible to devise a method of producing concave gratings from cylindrical matrices, a machine has been developed at the National Physical Laboratory for applying to a reciprocating concave blank a tool advanced by a 'Merton nut' driven by a screw of the pitch of the required grating.

Dr. A. C. Menzies, after referring to some recent work by Messrs. Hilger-Watts on the construction of fine-mesh metallic grids, went on to describe a modification of Sir Thomas Merton's process with the object of producing long gratings. This employs three successive operations. In the first, a short length of fine-pitch thread is engraved on a metal cylinder *B* by a diamond driven from a 'Merton nut' riding on a similar cylinder *A* on which a coarse thread has been engraved by a lathe. The two cylinders are connected together by a gear of ratio 32 : 1. In the second stage, a 'Merton nut' on *B*, with a diamond just ahead of it, extends the fine pitch thread as far as desired along the cylinder. The passage of the nut over the thread which it has ruled tends to produce irregular burnishing of the rulings. Although this would probably have little effect on the performance of a replica taken from the cylinder, it may be eliminated by ruling a third cylinder *C* by means of a 'Merton nut' riding on *B*, the two cylinders being coupled together by a 1 : 1 gear. This cannot introduce periodic error, although it may give rise to slight non-linearity of the rulings, which, however, is regularly repeated and therefore not objectionable. In all cases, one end-bearing consists of a 'Merton nut' on a 'neutral' thread, and the other of a similar nut on polished bar. A steel bar ruled by this method for a length of about nine inches was exhibited.

Dr. Menzies also directed attention to the probable value of the 'superfinishing' process, as used by Chryslers in the United States, in much reducing the time required to polish the metal cylinders preparatory to ruling by the Merton method.

In the discussion which followed, F. Twyman emphasized the desirability of comparative testing of existing gratings, especially some of the older ones reputed to be of 'good' quality. Prof. Curtis asked whether any correlation has yet been attempted between the results of the tests described by Mr. Guild and the performance of the grating in an actual spectrograph, to which Mr. Guild replied that this has not yet been possible as sufficient gratings of various qualities have not yet been available. Mr. Guild said that it is his object to establish such a correlation, and added that, although the tests might be capable of disclosing defects which are too slight to affect spectroscopic performance, such additional sensitivity is of great advantage in monitoring the development of the ruling process.

G. Sissen asked Mr. Guild whether it is possible by his wave-front shearing method to alter the inclination of the interfering wave-fronts, and consequently the spacing of the fringes. The latter replied that variation of fringe spacing is effected by displacing the double-image prism along the axis of the instrument. The direction of the fringes is, however, fixed relative to the direction of shear, in which respect Mr. Guild's beam divider is less flexible than that of Bates for general optical testing. Mr. Sissen then asked Dr. Sayce whether the thickness of the gelatine layer in the third stage of his process could be sufficiently increased to produce infra-red gratings, and received the reply that, although an increase in the thickness of the layer causes a slight departure from flatness, this is not enough to be detrimental in the infra-red region.

There was some discussion of the possibilities of the step-by-step method of grating ruling, which is attractive by reason of the elimination of the screw and its attendant errors. Various speakers referred to attempts on these lines, made in Germany, Sweden and Great Britain ; but it appears that none has been successful. The fundamental difficulty is thought to be that in any process of this type an accidental error of spacing will necessarily affect the whole of the subsequent rulings.

THE 1951 EXHIBITION OF SCIENCE

THE 1951 Exhibition of Science is splendidly housed, to the south of the Imperial College, in an extension of the Science Museum which is to form the nucleus of new permanent additions to the Museum buildings. A wealth of skill and decorative genius has gone to the making of a display which, despite some minor shortcomings, is an outstandingly good presentation of some of the main developments of pure science during recent years, with some appropriate historical background. It is planned as a continuous narrative (one might almost say a short course) and the round trip takes between one and two hours.

One enters by a maze-like tunnel with sound-proofed bays, in each of which a loud-speaker suggests that one is shrinking to atomic dimensions as illuminated models of graphite crystals expand successively ; at the end of the tunnel the visitor is on equal terms with an electron cloud. He is to see modern science from the atomic point of view.

The first stage of the journey around the exhibition itself deals with atomic structure. The diagrams and mural showing the history of the Periodic Table and its modern representation are good. The experiments on the electron are indifferent, chiefly due to lack of explanation as to why electric and magnetic deflexions occur ; and some of those listed are missing. There are some excellent animated diagrams illustrating radioactivity and nuclear physics, and two cloud chambers which work beautifully ; but why the catalogue should include under radioactivity a spectrometer "capable of refractive index measurements of 0·000001", whatever that may mean, is a mystery.

Next come sections on chemical structure, the nature of chemical bonds, and the structure of metals and crystals. These are on the whole magnificent, lending themselves admirably to representation by the modeller. The exhibits on enzymes are introduced curiously—first by a film-strip of a rugby footballer which is quite irrelevant unless it is intended as a miming for the word 'conversion' (though it is a penalty kick), and then by a model of a dancing class which could not be interpreted; but the exhibits themselves are clear enough.

Associated with the chemical section are a number of poorly adjusted ripple-tank experiments, which do not do justice to a well-known make of apparatus, and which are intended to lead up to the idea of X-ray diffraction by crystals. In this section also is shown the *EM3* electron microscope. The catalogue says this uses four magnetic lenses; as exhibited, it uses one electric lamp underneath one lantern slide, but nevertheless admonishes the public not to tamper with the controls. Is not a leading make of British electron microscope something to show proudly, in working order, on such an occasion ?

In the biological exhibits the emphasis is rather on living matter than on the organism as a whole; here again the modeller has had full scope and has done magnificently.

In the "Stop Press" section, pride of place must go to the exhibit on cosmic rays. This is fully documented, and tells the whole story from the first unaccountable electroscope leak to the most recent photographic plate work. It was worth the visit to see this exhibit alone, and to watch a counter-controlled chamber in action. Less impressive, but none the less excellent, is the smaller section on electrons in crystals, which explains the behaviour of luminescent materials clearly and effectively. Nimrod, the Ferranti electronic computer, is a good demonstration; the game it plays is simple, and any opponent who knows the rules has a good chance of success. The operator says it has a temper; but its face lights up after every move, whether advantageous or otherwise.

Nimrod, in fact, sets a standard by which many of the other 'working' exhibits might be judged. It really is in full working order, and it has someone in charge to explain what it is doing. Further, there is an excellent pamphlet published by Messrs. Ferranti, Ltd.*, which describes how it is constructed and how it works, and gives a little of the mathematical theory of digital computers. This pamphlet did not, however, seem to be available within the exhibition itself, which is a pity. There is a bookstall, at which expensive-looking commemorative jig-saw puzzles and scientific books quite unrelated to the exhibition are displayed; how much it could have contributed to the purpose of the whole if an explanatory pamphlet setting out details of some of the more striking individual exhibits (and moderately priced) had been on sale there! For the official guide-catalogue, useful as it is in explaining the exhibition as a whole, does not say very much that is helpful about individual items and is even confusing in places; in view of the fact that many items are neither clearly numbered nor effectively provided with displayed descriptive matter, this is a little disheartening. It says a great deal for the real quality of what there is on show that this criticism, which must be made, does not diminish one's admiration for the whole.

The writer was one of a small company of appreciative visitors who seemed to be pretty well outnumbered by the attendants. By all accounts, the exhibition has not so far touched the popular imagination, and there may be several reasons for this. It is the academic conversazione on the grand scale, with the exhibits clearly linked by one central idea, the structure of matter. Perhaps this is the reason, for people will pay to be entertained or impressed, but not to be instructed. Its very success in achieving its aims may well limit its popular appeal. Or it may be that an enterprise of this kind takes a long time to become widely known and appreciated, or even found. It is quite possible to emerge from the South Kensington subway, and be inside the exhibition on the history of the Science Museum itself, before realizing that it is not what you were seeking; though, of course, there is some discreet short-range guidance for the reasonably observant.

One feels that there is something of permanent educational value here, and a pleasing creation which would be worth a visit if only to see a scientific exhibition dressed in a Festival gaiety.

G. R. Noakes

GERMAN SOCIETY FOR ELECTRON MICROSCOPY

THIRD ANNUAL CONFERENCE

The German Society for Electron Microscopy held its third annual meeting in Hamburg during May 18–20. Although the meeting was convened as a national conference, invitations had been accepted by many foreign men of science, so that the conference took on a certain international flavour. Its success was due not only to the high quality of many of the contributions by German and foreign scientific workers, but just as much to the opportunities it offered to make, or renew, contacts between men and women of many countries.

The work of the conference was opened by H. Ruska with a general lecture on the more recent results of electron microscopy, mainly illustrated by examples taken from the biological and medical field. Stress was laid on combining results obtained by electron microscopy with those obtained by other means.

Only some of the large number of papers read (about seventy) can be mentioned here. Mathematical investigations into the properties of certain magnetic electron lenses were presented by Lenz and by Glaser, and experimental methods for the field determination in magnetic lenses were described by Lenz and by Wolff. A very simple 'electron-optical' bench arrangement, to facilitate experimentation, was shown by Boersch.

Instrument design has been pursued steadily during the last year, and Möllenstedt described a simple way of increasing the specimen penetration in the electrostatic instrument by placing the specimen into a chamber kept at $+50$ kV. with respect to earth, the gun operating at -50 kV.; a direct switch-over from 50 to 100 kV. can be made. The use of the electron microscope in electron diffraction studies has been extended through the development by Heise of an adaptor for glancing incidence work with the AEG–Zeiss instrument. The design of a small magnetic microscope built at the University of Munich was described by Kinder; this instrument is very similar to the RCA desk-model. An instrument of unconventional design was described briefly by von Borries. This instrument uses a single permanent magnet with two gaps in the iron circuit, one exciting the objective lens, the other the projector lens, the final image being free of image rotation; the magnification of the projector lens can be varied continuously by an axial movement of the pole piece insert. Further experiments with Boersch's filter method, in which the majority of the inelastically scattered electrons which reduce the image contrast in electron microscopy and in electron diffraction are eliminated, were described by Rang, who used an electrostatic lens to obtain the required critical deceleration.

---

* *Faster than Thought*: the Ferranti Nimrod Digital Computer. Pp. 40. (Hollinwood: Ferranti, Ltd., 1951.) 1s. 6d.

The usefulness of stereoscopy in the interpretation of complicated structures was demonstrated by Helmcke, who also applied the methods of photogrammetry to a quantitative evaluation of stereograms, and by Grasenick.

The problem of the 'tolerance dose' without specimen destruction was discussed from various aspects. Boersch estimated that hydrogen atoms will always remain invisible; but that carbon atoms might possibly be made visible if the resolving power could be increased sufficiently far. Experimental investigations by König gave a much more pessimistic picture; specific loads of 10^4 to 10^5 Wsec./cm.^{2} at the specimen already lead to a partial breakdown of the more complicated materials. Rang showed that by correct choice of the observation screens optimum conditions regarding specimen load during focusing can be maintained.

Interesting details were given by König of the 'carbon skin' method of obtaining three-dimensional 'replicas' of substances which do not stand the high beam intensities often required in their imaging. The specimen to be coated is placed on the aluminium anode of a glow discharge maintained in benzene vapour of about 1 mm. pressure. The carbon coating formed is later 'hardened' either by subjecting the coated specimen in the electron microscope itself to a high beam current, or by keeping it for some time in a vacuum oven at 400° C. The original specimen can then be dissolved, or evaporated out, leaving the carbon skin intact; this gives a faithful representation of the original, as was proved by stereograms of diatom replicas shown by Helmcke.

Surface structure, phase changes and crystal growth phenomena at elevated temperatures in steel and iron–nickel alloys were demonstrated convincingly by Rathenau, using the emission electron microscope; other applications of electron microscopy to metallurgical problems were discussed by several authors. Grasenick has studied crystal growth in magnesium oxide, and Helwig the formation of zinc and cadmium oxides. Several papers described the structures of activated aluminium oxides. Rang and Schluge, as well as Bernard, and Möllenstedt, showed how the Bragg diffraction lines appearing in many electron micrograms of crystalline materials can be co-ordinated with certain lattice positions.

A number of papers dealt with the methods of preparation of biological material; Kellenberger described a critical study of various methods of preparing *B. coli* for the electron microscope, and Winkler an investigation into the method of fixation which gave closest agreement with the light optical picture. The varying success of the 'freeze-drying' method was discussed by Studer and others. Contributions to the study of collagen and reticulin fibrils were presented. Further papers dealt with the reaction of bacteria to certain treatments (for example, of T.B. bacilli to streptomycin) and other cytological questions, and with the first electron microscopical representations of new material.

Progress in the preparation of thin sections of tissues was reported by several workers. Kellenberger described the design of a new microtome (made by Trüb-Täuber, Zurich), cutting reproducibly to 0·05 micron, and illustrated this by slides of thin sections through nerve fibres of frogs and neuro fibrils. Bretschneider uses a modified C.I.C. microtome; he considers that the problem of thin sectioning is no longer one of microtomes but of the technique of fixation; this he described in detail. (Of eighteen mixtures investigated, a composition of paraffin wax, beeswax and carnauba wax was found most successful.) This talk, too, was illustrated by interesting slides. Bernhard discussed investigations on cancer cells using the thin-sectioning technique; the interpretation of earlier American results, showing virus particles in cancer cells, could not be confirmed, as most virulent cancer cells investigated were free of these bodies. Hence, normal cells were studied, in which several new features were discovered, the function of which is still unexplained. Mölbert and Beyersdorfer also described a new microtome (made by Jung, Heidelberg), and discussed the technique of its use. They found that an after-treatment of the thin sections by an electrical discharge in air of 0·05 mm. mercury pressure made them more resistant to the electron beam.

Many other subjects were discussed, for example, polymerizing methyl methacrylate replicas, investigations on textile fibres, rubbers and plant cells, size measurements of sub-microscopical crystals, fine-grain photographic emulsions and studies of surface contamination phenomena with Muller's point projector microscope.

An exhibition of photographs and of new instruments was held in conjunction with the conference. Besides microscopes, microtomes and vacuum accessories, four electron microscopes were on show. All these instruments were distinguished by a high standard of craftsmanship employed in their manufacture, but they were expensive by our standards. The Philips electron microscope has been exhibited in Great Britain on several recent occasions, and does not, therefore, require any further description; but the AEG–Zeiss electrostatic instrument will not be known to many workers here. This machine uses electrostatic lenses throughout. The need for frequent cleaning of the lenses has been greatly reduced through a built-in 'stigmator', which compensates the astigmatism caused by dirt particles getting into the lenses. Three magnifications can be selected by using the two fixed projector lenses singly or in combination; an additional diffraction lens is provided. Siemens demonstrated two instruments, their standard three-lens type for 100 kV., and a new simplified type for 60 kV. Both types are post-war developments of the original Siemens instrument Both new instruments employ a revolving projector lens head, which allows any of four projector lenses to be brought quickly into operation. Many other improvements over the old type are incorporated, for example, grease vacuum joints are replaced by rubber seals. G. LIEBMANN

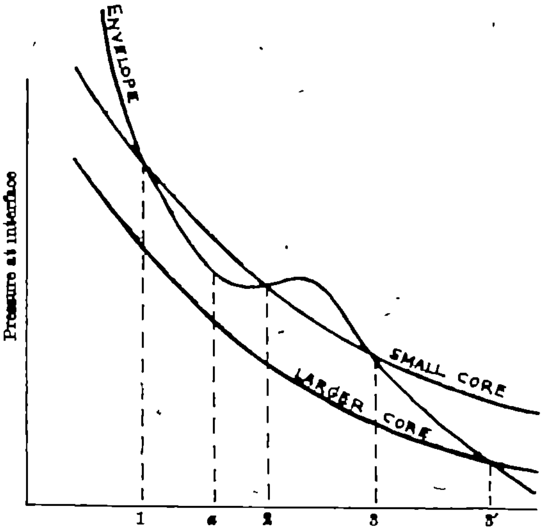
Hydrogen Exhaustion and Explosions of Stars

It is a well-established fact that energy production in stars is due to the thermonuclear transformation of hydrogen into helium. Since hydrogen forms about one half of normal stellar material, the rate of its consumption, that is, the luminosity of the star, determines the stellar life-span; in the case of our sun it can be calculated to be about fifty thousand million years, which is very long as compared with the estimated age of the stellar universe. Since, however, stellar luminosity (hydrogen consumption) increases very rapidly with stellar mass (hydrogen content), the life-spans of brighter stars are considerably shorter. Thus stars of about zero absolute magnitude would run through their hydrogen evolution in a few thousand million years, that is, in a period of time which is generally accepted as representing the age of our universe. Indeed, we notice that the stars of zero absolute magnitude seem to represent a demarcation line in the stellar population of our galaxy. Thus the main sequence of the Russell–Hertzsprung diagram shows a noticeable discontinuity at that particular point. The brighter stars are very scarce in space and are in a state of rapid axial rotation; the fainter stars are very abundant and scarcely rotate at all. Also, within stellar population II, as defined by Baade (the regions of the galaxy where no interstellar material is present), the upper part of the main sequence is completely absent.

All this suggests that zero absolute magnitude divides the main sequence into the older (lower) part containing the original stock of stars formed almost simultaneously a few thousand million years ago, and the younger (upper) part consisting of stars formed by condensation processes at various more recent epochs. We may also notice that zero absolute magnitude serves as an apex from which the main sequence of stars branches out into 'swollen-up' stellar types such as pulsating variables and red giants in general, and 'shrunken' stellar types which include Wolf–Rayet stars, nuclei of planetary nebula, white dwarfs, and various types of exploding stars (U-Geminorum, recurrent novæ, ordinary novæ and supernovæ). It is difficult to escape the impression that stars deviating from the main sequence are those which have run out of their original hydrogen supply, a situation which forces them to go through 'unusual' final stages of their evolutionary life. One would expect, in fact, that all these stars would have comparable masses (at least at the stage when they leave the main sequence) of the order of magnitude of three sun masses and about the same total life-span of a few thousand million years. This conclusion finds support in the Kukarkin–Parenago relation, according to which the intensity of periodic stellar explosions (U-Geminorum stars, and recurrent novæ) is directly proportional to the period between explosions. This relation, indicating a constant total rate of energy production, would be difficult to understand for stars of different masses and, consequently, different central temperatures.

If we look at this problem from the point of view of possible stellar models, we find that an ageing star would be expected to develop a so-called 'shell-source' of nuclear energy. In fact, when all the material in Cowling's convective zone supplying fresh fuel for nuclear reactions in the centre is completely dehydrogenized, the reaction would transfer itself into a spherical layer between the isothermal helium core, and the radiative hydrogen-rich envelope. The properties of such shell models have been studied by many authors[1], with rather interesting results. It has been found that an attempt to fit a small isothermal core into a radiative envelope (with the temperature and pressure continuous at the interface) results generally in several possible solutions. One of these gives a star of extremely large radius which can be considered as a tentative model of a red giant (A. Reiz). The other two solutions lie rather close to one another, representing stars of more or less normal size (Hayashi). However, when the fraction of the stellar mass in the core increases (due to the progressive nuclear reaction) these two solutions disappear (S. Chandrasekhar), leaving the evolving star in an odd position of 'not knowing what to do'.



Dependence between the pressure at the interface and its radius for the base of the radiative envelope and the surfaces of two isothermal cores. (Schematic drawing)

The situation is represented schematically in the accompanying graph showing three intersections (1, 2, 3) for smaller cores and only one intersection (3′) for larger cores. The disappearance of two intersections for larger cores means physically that it is no longer possible to fulfil the continuity conditions both for temperature and pressure. If we 'force' a solution for some interface-radius a, we find an inversion of pressure and the star will start to collapse. We can, of course, stabilize the model by raising the temperature (and hence the pressure) at all points of the core; but this will produce a non-stationary thermal state, and lead to gradual heating of the inner layers of the hydrogen-containing envelope. The situation is rather analogous to that in an ordinary electric bell, where the clapper can neither stay at the electromagnet nor at the electric contact. It is difficult to predict the behaviour of the model without rather elaborate hydrodynamical calculations (cf. G. Gamow and C. Longmire); but it is apparent that at this point of evolution the static model must go over into some kind of periodic motion. When the stability conditions are just exceeded, we would expect short-period motion with small amplitudes. As the core grows, both period and amplitude would be expected to become larger and larger. Thus, we have here a picture which may be useful for the explanation of the Kukarkin–Parenago relation, provided we consider different *U*-Geminorum stars as successive evolutionary stages of a single stellar mass. It may, indeed, easily happen that the 'oscillations' described above will result in periodic convectional instabilities. In this case a rapid mixing of cool hydrogen from the envelope with hot helium from the core will result in periodic nuclear explosions of the star. There is also the possibility that similar instabilities may develop in 'swollen-up' solutions of the shell-model. If the resulting central explosions are comparatively weak, they will not show through the thick body of the star and may act as a 'buzzer' mechanism for maintaining regular stellar pulsations.

It is too early to say whether or not the above views will lead to a correct explanation of the dynamical states of ageing stars. The study of the hydrodynamical equations involved in the problem is extremely difficult, and can be done only by means of modern electronic computers. Work in this direction is now being done by the author and his colleagues, A. Carson, G. Keller, C. Longmire, N. Metropolis, L. Peck and R. Richtmeyer, with the hope of having solutions run on a new electronic computer ('Maniac') under construction at the Los Alamos Scientific Laboratory.

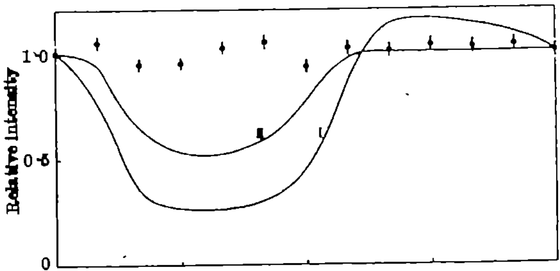
Evidence of Multiple Meson Production

Direct evidence of the production of several mesons by a single primary proton in cosmic rays has been obtained by cloud chambers and photographic plates[1], and indirect evidence by observations of a relatively low average energy of mesons at sea-level[2,3]. Further indirect evidence is furnished by the absence of azimuthal intensity variation obtained as a result of the experiment described here.

Four triple-coincidence counter telescopes, each differing in azimuth by 90°, were used at sea-level, geomagnetic latitude 43·5° S., the middle counter in each telescope having 5 cm. of lead on either side of it. The angle subtended by each telescope was 13° × 3·5°, the larger angle being in the vertical plane, and the zenith angle was 60°. Intensity measurements were made at azimuth intervals of 30°, the average counting-rate being 16·00 per day. From the measured counting-rates, 3·75 counts per day were subtracted, this figure being taken as the shower counting-rate, obtained using a telescope identical with the others except that the middle counter was moved out of line.



Cosmic ray intensity at sea-level

Theoretical curves I (single meson production) and II (including meson decay). ○, observed intensities, showing ± standard error

From the shadow cone theory[4] the primary cut-off momentum interval explored was calculated to be from 3,600 MeV./*c* at azimuth 270° to 16,000 MeV./*c* at 120°.

The measured intensities, after shower correction, are plotted in the accompanying graph, each point being based on approximately 1,700 counts. Curve I is calculated using a primary momentum spectrum $dN = KP^{-3}dP$, the exact form of which is not important, assuming each primary gives rise to a single meson capable of penetrating to sea-level, and is normalized to unit intensity at 0°, corresponding to an observed corrected value of 12·19 ± 0·38 counts per day. Curve II is drawn taking into account the effect of meson decay. It is clear that an asymmetry is to be expected, which is at variance with the observations, for only one point differs from the mean of 12·25 by more than twice the standard error.

The observed uniform intensity at all azimuths may be explained by assuming that several secondaries are produced by each primary, and that the maximum momentum of a secondary produced by a primary with momentum between 3,600 and 16,000 MeV./*c* is less than the momentum loss in traversing the inclined atmospheric path, that is, less than 4,000 MeV./*c*. If the effect of meson decay is considered, this maximum may be increased slightly, as the probability of a meson of initial momentum 5,000 MeV./*c* penetrating to sea-level is less than 0·1. This conclusion appears to be in agreement with previous results[1-3].

A Convenient Synthesis of Carbon-labelled Benzene

Several syntheses of benzene and its simple derivatives labelled in the nucleus with isotopic carbon have been described[1-5]. The aluminium-halide catalysed rearrangement of alkyl *cyclo*pentanes to *cyclo*hexanes[6,7] affords an attractive route to benzene and its homologues, and we now present a preliminary report of an examination of this method as it applies to benzene itself.

*cyclo*Pentane carboxylic acid, prepared by the carbonation of *cyclo*pentyl magnesium chloride at − 30°, was reduced by lithium aluminium hydride[8] to *cyclo*pentyl carbinol (b.p. 159–161° ; n_D^{21} 1·4567) in an overall yield of 81 per cent from carbon dioxide. Dehydration of the carbinol over activated alumina at 320° gave a mixture of unsaturated hydrocarbons which after hydrogenation over a nickel catalyst gave a 91 per cent yield of a mixture of methyl *cyclo*pentane and *cyclo*hexane (n_D^{20} 1·4149), shown by infra-red and refractive index measurements to contain approximately 30 per cent *cyclo*hexane. This mixture was treated in a sealed tube at 75° during four hours with water-promoted aluminium chloride[6] ; the recovered hydrocarbon (98 per cent ; n_D^{20} 1·4228) contained 81·5 per cent *cyclo*hexane. Selective dehydrogenation of the *cyclo*hexane content of this mixture was carried out over a platinum-charcoal catalyst[9] at 350° ; in this way recoveries of better than 92 per cent of a product containing about 76 per cent benzene, 20 per cent methyl*cyclo*pentane and 4 per cent *cyclo*hexane were obtained. The platinum–porous pot catalyst described by Berl and Koeber[10] gave satisfactory results with pure *cyclo*hexane, but the presence of even a few per cent of methyl*cyclo*pentane markedly inhibited dehydrogenation of the *cyclo*hexane present. Benzene was isolated from the mixture by formation of the clathrate compound with ammoniacal nickel cyanide solution[11,12]. The recovery of benzene from the above, and similar artificial mixtures, was about 89 per cent, the product having n_D^{20} 1·5011 and melting point 5·5°.

In this manner an overall yield of benzene from carbon dioxide of approximately 45 per cent has been obtained, which may be further improved by carrying out the aluminium chloride catalysed isomerization of methyl*cyclo*pentane at a lower temperature[7] for a longer time, and by recovering and recycling the *cyclo*hexane and methyl*cyclo*pentane which do not react with ammoniacal nickel cyanide. A full account will be published elsewhere.

I am indebted to Mr. R. J. Warne for considerable assistance in the concluding stages of this investigation, and to Mr. J. L. Hales for the infra-red measurements. This communication is published by permission of the director of the Chemical Research Laboratory.

Action of Dilute Sulphuric Acid on Magnetized Iron

FROM some observations on the chemical action of dilute sulphuric acid on magnetized iron, it has been stated[1] that, in addition to hydrogen, oxygen is present in considerable quantities, whereas with unmagnetized iron no such phenomenon occurs. We have investigated this further with an apparatus specially designed to exclude atmospheric oxygen and to prevent its subsequent diffusion into the materials. The results obtained with Swedish commercial iron indicated such an effect of the order of magnitude of only 10^{-3} to 10^{-4} by volume[2].

To narrow the limits still further, specimens of spectroscopically pure iron, first heated in an atmosphere of hydrogen and then degassed *in vacuo*, were allowed to react in a magnetized state. The gas analysis, performed with catechol – ferrous sulphate[3], gave colorimetrically a negative result, that is, an oxygen content certainly less than 10^{-6} by volume, which result was obtainable with unmagnetized specimens as well.

Solidification Curves and Crystal Spacings of Binary Fatty-acid Mixtures

THE solidification curves of binary systems formed by adjacent even-numbered saturated fatty acids show, besides a minimum at about 73 mol. per cent of the lower-melting acid, an inflexion at the equimolar composition. To explain this departure from the Roozeboom classification of solid solutions[1], various investigators have assumed the formation of a compound by the two components of the system[2], an obvious assumption in view of the tendency of fatty acids towards association established by Robertson's cryoscopic studies[3]. However, compound formation has not been adequately verified by the results of X-ray measurements of fatty-acid mixtures, and Slagle and Ott[4], having found only one long crystal spacing d_1 instead of two d_1 spacings in mixtures other than equimolar, suggested a continuous series of solid solutions. The peculiar shape of the solidification curves of fatty acids was attributed by them to polymorphism.

During the present investigation, d_2 and d_3 short crystal spacings not reported hitherto for fatty-acid mixtures have been determined in addition to d_1 spacings in C_{12}—C_{14}, C_{14}—C_{16} and C_{16}—C_{18} acid-pairs, using a Philips Geiger X-ray spectrometer. Specimens were prepared by melting the samples on glass and rapid cooling. No changes of spacings due to polymorphism were observed. Single sharp values for d_1 spacings computed from third-order diffraction lines were obtained in each case ; but these values were of no particular interest, being reproducible only to ± 0·5 A. On the other hand, values for d_2 and d_3 spacings, which denote lateral distances between the fatty-acid chains, were reproducible to ± 0·01 A.; and while d_2 remained practically the same for all compositions of any given acid-pair, d_3 showed small but distinct changes. As can be seen from the example of C_{12}—C_{14} acids (cf. table), d_3 spacings of the majority of mixtures are uniformly greater than those of either pure component. However, while the mixture containing 5 per cent myristic acid shows a pronounced increase in d_3 as compared with pure acids, mixtures containing up to 25 per cent lauric acid show none. A mixture of 90 per cent lauric and 10 per cent myristic acid has the same d_3 spacing as a mixture of 70 per cent myristic and 30 per cent lauric acid. C_{14}—C_{16} and C_{16}—C_{18} acid-pairs showed similar although less pronounced changes in d_3 spacings for varying compositions.

CRYSTAL SPACINGS OF MIXTURES OF LAURIC AND MYRISTIC ACIDS

Lauric acid (m.p. 44·1° C.) Weight %	Myristic acid (m.p. 54·2° C.) Weight %	Crystal spacings (in A.) d_1	d_2	d_3
100	0	27·0	4·12	3·73

5	95	31·5	4·13	3·74
0	100	31·5	4·12	3·73

* Equimolar mixture.

These changes in d_3 spacings acquire significance when compared with the phase diagram for C_{12}—C_{14} acids determined by Jantzen[5], who, on subjecting mixtures of the above acids to very slow cooling (0·2° C. per 24 hr.) to approach equilibrium, obtained the only available solidus–liquidus curve of a binary fatty-acid system. His diagram, as reproduced and interpreted by Bailey[6], indicates maximum inter-solubility in the solid state in mixtures containing up to 20 per cent myristic acid on one side and up to 35 per cent lauric acid on the other, these percentages being, according to Bailey, probably too high. In the remaining range there are partial solid solutions and compound formation. The accompanying table shows that the addition of 10 per cent myristic acid produces the same increase in d_3 spacings as does the addition of 30 per cent lauric acid. It seems justifiable to correlate the above figures with those obtained from Jantzen's diagram, since it can be assumed that maximum intersolubility of two fatty acids coincides with the maximum packing density, which is determined to some extent by d_3 spacings. Both results imply that the longer-chain myristic acid is less soluble in the shorter-chain lauric acid than is lauric in myristic, which is not unexpected.

It appears from Jantzen's diagram that the question of compound formation versus continuous series of solid solutions resolves itself into the problem of determining the areas of various phases existing in the solid state, and we suggest: (*a*) that the boundaries inside which partial solid solutions and compound formation occur are indicated by increased d_3 spacings; (*b*) that an improved technique of measuring short crystal spacings of mixtures of fatty acids may help in defining the above boundaries, not only more conveniently, but perhaps even more accurately than the lengthy procedure of determining solidus–liquidus curves. Solidification curves obtained without achieving equilibrium in the system are of little use in this respect.

We are indebted to Prof. F. J. Llewellyn, of Auckland University College, and to Dr. K. Strzemienski, Soil Bureau, N.Z. Department of Scientific and Industrial Research, for discussion.

C_{20-22} Unsaturated Acids of Butterfat

APART from the fact that Bosworth and Sisson[1] established the presence of arachidonic acid in butterfat, there is little, if any, precise information (cf. Bosworth and Brown[2]) regarding the nature of other C_{20-22} unsaturated acids. The purpose of this communication is to record the results of work in progress which support Hilditch's opinion[3] in regard to the C_{20-22} unsaturated acids of butterfat that, "while arachidonic acid may be the chief component, there are probably other polyethenoid (tetra- and pentaene) acids present, possibly of the C_{22} as well as of the C_{20} series".

The samples of butterfat used in the present investigations were obtained through the courtesy of the Dairy Research Institute, Massey Agricultural College. Sample *A*, churned in April 1945, was from a mixed herd at the College, while sample *B*, churned in May 1947, was from the Rangitaiki Plains Dairy Co.

The isolation of the C_{20-22} fractions was achieved by high-vacuum distillation of the methyl esters using a Vigreux column (210 cm. × 6 cm.) for the

* Constants determined on methyl esters. † Includes also some hexaene acid, $E\ (1\%, 1\ \text{cm})\ 375\ \text{m}\mu = 10{\cdot}5$

preliminary concentration and a smaller (240 cm. × 4·5 cm.) column for the final purification. For sample *A*, the methyl esters from the most soluble acids prepared by crystallization from acetone at − 50° C. were used. In the case of sample *B*, the C_{20} concentrate was prepared from the methyl esters of the total fatty acids. The concentrate thus prepared was first freed from saturated acids by crystallization three times from 15 volumes of acetone at − 30° C. After redistillation of the soluble portion, the corresponding acids (*B*1) were crystallized three times from 10 volumes of acetone at − 78° C. to separate the highly unsaturated acids *B*2.

The results given in Table 1 are based on the alkali isomerization technique as described by Beadle and Kraybill[4]. As, however, no value for *E* (1%, 1 cm.) was available for the pure pentaene acids, it was necessary to prepare a pentaene concentrate by chromatographic adsorption on alumina using as a solvent petroleum ether, b.p. 50–60°, containing 1·5 per cent ether. The concentrate thus prepared, to judge from the iodine value of the methyl esters (366·9), contained 57·8 per cent pentaene acids, assuming that tetraene and pentaene acids only were present. From the absorption characteristics of this concentrate after alkali isomerization by the Beadle and Kraybill[4] technique, the absorption characteristics of the pure pentaene acid were calculated by substituting the known values for the tetraene acid as given by these workers (cf. Table 2).

Table 2. Absorption Characteristics of a C_{20} Pentaene Concentrate of Butterfat

	E (1%, 1 cm.) 234 mμ	268 mμ	316 mμ	348 mμ	375 mμ
Before isomerization	42·0	41·5	trace	trace	trace
After isomerization	551·2	453·1	296·0	145·7	trace
Calculated values for pure pentaene acid	448·8	321·7	347·1	252·1	—

Widmer and Holman[5], using for isomerization 23 per cent potassium hydroxide–glycol for 8 min. at 180° C., found by interpolation of the values for diene, triene, tetraene and hexaene acids, a value of *E* (1%, 1 cm.) 348 mμ for the pentaene acid of 300. We have found, however, for our pentaene preparation isomerized by the Widmer and Holman[5] procedure a value of *E* (1%, 1 cm.) 348 mμ of 471, corresponding to a value of *E* (1%, 1 cm.) 348 mμ of 814 for the pure acid. The difference between our high value and the much lower value of Widmer and Holman[5] may be due to the fact that the hexaene standard which they used for interpolation was impure.

The absence of a pure pentaene standard, together with the difficulty of separating the methyl esters of the higher unsaturated acids into fractions containing the same number of carbon atoms, imposes limitations on the results now presented. Nevertheless, general confirmation of the presence of monoene, diene, triene, tetraene and pentaene acids has been obtained by chromatographic adsorption analysis on an alumina column using petroleum ether and petroleum ether–ether mixtures respectively for development and for elution of the chromatogram. Limitations have also been imposed by the quantities of material available. The whole fraction, *B*1 concentrate, for example, amounted to 0·4 per cent of the original butterfat, while the other fractions used formed considerably smaller proportions. Larger quantities of material are now being examined, and it is hoped that further clarification of the nature of the C_{20-22} acids will result.

Effect of Altitude on the Estimation of 'Crude Fibre'

In the estimation of 'crude fibre' by the Weende method, no provision has been made for the effects of altitude and consequent lowered boiling points of the acid and alkali. The Kabete Laboratories are situated at an altitude of 6,200 ft. and the solutions boil at 94° C.

In order to find the effect of the reduced boiling temperature on the 'crude fibre' estimation, ten samples of material of varying fibre contents were taken to Dar-es-Salaam and 'crude fibre' estimations carried out. Estimations were also made on the same samples by the same worker at Kabete. The results are summarized in the accompanying table, the error involved being calculated in each case as a percentage of the results obtained at sea level.

Sample	Crude fibre in dry matter (per cent) at sea-level	at 6,200 ft.	Percentage error
Maize meal	2·229 ± 0·066	2·705 ± 0·071	21·35
Oats	10·677 ± 0·267	11·846 ± 0·220	10·95
Bran	14·017 ± 0·232	14·727 ± 0·133	5·07
Clover spp.	19·085 ± 0·201	20·232 ± 0·106	6·01
Lucerne	25·980 ± 0·300	27·497 ± 0·102	5·84
Grass			
sample 1	30·455 ± 0·122	32·040 ± 0·094	5·20
,, 2	31·212 ± 0·432	32·897 ± 0·267	5·40
,, 3	32·610 ± 0·227	34·637 ± 0·174	6·22
,, 4	35·372 ± 0·016	37·537 ± 0·389	6·12
Sawdust	64·345 ± 0·200	68·920 ± 0·246	7·11

The extent of the error varies with the type of material, the cereal grains showing greater percentage errors than the other samples examined. There is quite close agreement between the errors found for the legume and grass samples, the average percentage error for the six samples being 5·80 per cent with a standard error of ± 0·17 per cent.

There are three ways of correcting this error: (*a*) by increasing the duration of the boiling; (*b*) by increasing the concentrations of acid and alkali; (*c*) by carrying out the estimation by the standard procedure and applying a correction factor. (*c*) is the most convenient of the three, as (*a*) and (*b*) would involve trial-and-error technique to find the correct increase in duration of boiling or concentration of acid and alkali. It is, also, most liable to error since, as shown above, the percentage error and therefore the correction factor vary for different materials. From the above figures it would seem, however, that the greatest variation occurs in materials with low-fibre content, so that the absolute error involved would be small.

It is probable that the estimation of lignin at high altitudes would be similarly affected, possibly to a greater extent in view of the longer boiling periods and higher acid concentration involved.

Positive Bromine Ions ?

IN a recent communication[1,2], we described experiments in which bromine migrated towards the cathode from acid HOBr solution across paper-collodion membranes. We interpreted this migration as evidence of 'positive bromine ions' (Br^+ or H_2BrO^+ ions) that were present in these acid solutions. Further experiments revealed, however, that there was a considerable electro-endosmosis across the membranes in the direction of the cathode, and it became necessary to reconsider our results.

We avoided the use of membranes by placing two inverted U-tubes between the beaker containing the HOBr solution and those containing sulphuric acid and acting as electrode compartments. The U-tubes were filled with organic fluids lighter than water and able to react with active bromine. A solution of fluoresceine or carotine in butanol served for this purpose, and in both cases the anodic U-tube changed colour, whereas the cathodic one did not. Pure butanol also reacted with active bromine, and analysis revealed here, too, that migration was directed towards the anode. In each case the bromine accumulated to a greater extent in the anodic U-tube than in a control tube filled with the same reagent and immersed in the HOBr solution but without current passing through it, while the reaction at the cathodic side was less than that in the control tube, being, in fact, imperceptible.

This shows that we were able to detect the presence of OBr^- anions even in our 25 per cent sulphuric acid solution, where, using the new dissociation constant of HOBr as determined by Silov[3], the OBr^- concentration was only 10^{-18}. As no reaction whatever was observed on the cathode side, we may safely assume that the concentration of positive bromine ions, if such do exist, must be less than 10^{-11} in our $N/10$ HOBr solution. We also tried to use such compounds as indicating reactants which do not react with HOBr unless it is acidified, hoping to exclude the reaction of the OBr^- ion. Refractometric measurements with xylene and with ethylbenzoate showed no significant effect, and a green solution of nitrosobenzene in butanol failed to give any colour reaction either. The voltage was about 300 V. D.C. and the current varied according to the conductivity of the organic fluid from a few microamperes to milliamperes. Thus, there is no direct electrochemical evidence for the existence of positive bromine ions.

We happened to prove, however, that fluoresceine migrates towards the anode in solutions more acid than pH 3·5, and eosine behaves similarly. We suggest that the ring oxygen atom may be responsible for this effect, acting as centre of an oxonium ion.

A detailed account of our results will appear in *Magyar Kémiai Folyóirat*.

Conservation of Amino-acid Chromatograms

IN filter-paper partition chromatography, the ninhydrin reaction has been used almost exclusively for the identification and quantitative assay of amino-acids. One of the chief disadvantages of the blue pigment formed in this reaction is its rapid fading on filter-paper chromatograms. This makes it difficult to construct permanent or semi-permanent reference maps from which not only the type of amino-acid, but also the approximate quantity of the unknown mixture, can be deduced.

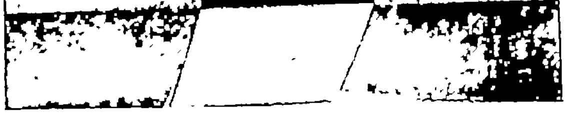
It was found that the blue pigment could be rendered a great deal more stable by coupling it with a metal. This observation was made independently in our two laboratories and has led to a study of the metal derivatives of the blue pigment. All amino-acids form red pigments, except proline and oxyproline which form a yellow metal complex. These findings are summarized in the table. In addition to the metals mentioned in the table, nickel salts also yield red pigments very similar to cadmium.

Amino-acids	Zn''	Cd''	Co''	Cu''
Proline	yellow	yellow	brown	yellow ochre
Oxyproline	grey	yellow	light brown	
Alanine Glycine Serine Threonine	brick red	port wine red	chestnut	salmon
Phenylalanine	red	red ochre	brown	red ochre
Tryptophane	red	orange	brown	red ochre
Other amino-acids	red	port wine red	chestnut	salmon

Apparently the red complex salt is formed from two molecules of diketohydrindylidene-diketohydrindamine (the blue pigment) with one atom of the metal being held between the two nitrogen atoms. Hence it would be correctly described as triketohydrindyliden-2-amino-1-oxy-indenon(3)-metal, for which a structural formula has been suggested elsewhere[1].

In practice, the red complex of the blue pigment is produced by dissolving a salt of one of the metals in methanol or ethanol and spraying each blue spot on the chromatogram with the reagent; on evaporation of the solvent, the corresponding red, reddish-brown or salmon-coloured pigment is formed. The following reagent, which keeps indefinitely, has been found useful: to 1 ml. of a saturated solution of copper nitrate add 0·2 ml. of 10 per cent (v/v) nitric acid and make up to 100 ml. volume with 95 per cent ethanol. This makes approximately a 0·8 per cent solution of copper nitrate at room temperature.

The accompanying photograph illustrates the results which can be obtained. A strip of filter-paper was saturated with a weak solution of alanine, dried, sprayed with 0·1 per cent ninhydrin and heated at 37° C. for 30 min. to develop the blue colour. A centre section of this strip was cut out and put aside, and the remainder was sprayed with the copper reagent. The cut-out section was now replaced and the strip photographed (Fig. 1). The



strip was placed on the work bench in front of the window for one month and then re-photographed on the same film under identical lighting conditions (Fig. 2). The centre section, which had not been treated with copper, had faded completely in this time, whereas the outer portions of the strip show that the red pigment had remained the same.

The red copper pigment, though relatively stable on dry filter-paper where it is out of contact with other ions, is a very unstable salt in aqueous solution. It dissociates into the blue pigment on passing on to the alkaline side of pH 7·0, this change being reversible provided the alkalinity does not exceed pH 9·0. Ions that compete for copper can also dissociate the complex reversibly; for example, the copper pigment does not form in the presence of tartrate or citrate ions, or in the presence of thiourea which forms a non-ionized copper complex. Free hydrogen ions cause rapid bleaching of the red copper complex.

The optimum conditions under which amino-acid chromatograms can be preserved, therefore, are as follows: (1) the paper must be washed; in practice, the method of Novelle[2] has given satisfactory results; (2) the ninhydrin reagent should not contain a citrate buffer like the reagent proposed by Moore and Stein[3]; (3) after spraying with the copper reagent, the red spot must be momentarily exposed to ammonia vapour in order to neutralize traces of free acid; and (4) the chromatogram should be dipped into a saturated solution of methyl methacrylate polymer 'Perspex' in chloroform to prevent moisture and atmospheric contaminants, such as volatile acids, from acting upon the pigment.

Application of Buffered Solvent Systems to the Detection of Aromatic Acids by Paper Partition Chromatography

The appearance of aromatic acids during the metabolism of phenylalanine in bacterial cultures has been investigated. In view of the fact that these intermediates are most probably formed in very small amounts and afterwards metabolized rapidly, a sensitive qualitative technique is required for their detection; a chromatographic separation of certain aromatic acids was therefore attempted.

The separation of aromatic hydroxy compounds has been effected by Evans, Parr and Evans[1] using butanol – pyridine mixtures in saturated sodium chloride solution, and Kelemen, Tanos and Halmagyi[2] have separated certain *p*-amino aromatic acids with *n*-butanol. Bray, Thorpe and White[3,4] used benzene–acetic acid–water and chloroform–acetic acid–water mixtures for the separation of hydroxybenzoic acids.

Various workers[5-7] have shown that movement of acids on paper can be restricted to more discrete spots if acid or alkali is added to the developing solvent. Although theoretically either should be applicable in the case of aromatic acids, owing to their low volatility, considerable difficulty was, in fact, observed in the subsequent removal of acetic or hydrochloric acid from the paper. The addition of ammonia or organic bases did not in itself produce very good results, presumably due to the loss of buffering action due to their marked volatility. Accordingly, ammonia/ammonium carbonate buffer solutions (1·5 *N* with respect to each) were employed instead of ammonia solution alone to saturate the *n*-butanol in the mobile phase. This resulted in the production of very small spots with little or no tailing.

No. 4 Whatman Paper Used; Chromatograms run at 15° C.

	R_F values		
	n-Butanol ammonium carbonate buffer	*n*-Butanol ethanol ammonium carbonate buffer	*n*-Butanol benzene ammonium carbonate buffer
Anthranilic acid	0·26	0·41	0·20
p-Aminobenzoic acid	0·09	0·15	0·04
p-Hydroxybenzoic acid	0·10	0·23	0·08
Mandelic acid	0·28	0 45	0·22
Hippuric acid	0·31	0·46	0·23
o-Coumaric acid	0·27	0·42	0·20
Sulphanilic acid	0·11	0·19	0·04
Cinnamic acid	0·62	0·62	0·41
Phenylpropionic acid	0·57	0·67	0·44
Phenylacetic acid	0·44	0·58	0·35
Benzoic acid	0·41	0·58	0·34

In the first column of the accompanying table are given R_F values for a number of aromatic acids developed with *n*-butanol saturated with the ammonia buffer. Similar success in limiting the size of spot has been attained in chromatograms of keto-acids run as the corresponding 2,4 dinitrophenylhydrazones, and the homologous series of dibasic acids from oxalic to suberic.

The separation of certain of the acids under these conditions is not great and additions were made to the *n*-butanol–ammonium carbonate buffer in an attempt either to accelerate the rate of the fast-moving acids or to depress the rate of flow of the slower-moving ones. Ethanol was of considerable use in the former respect (cf. column 2 of table), while benzene was effective in the latter (cf. column 3). The constitution of the two mixtures was as follows: *n*-butanol 40, ethanol 11, buffer 19 (v/v); and *n*-butanol 80, benzene 5, buffer 15 (v/v). The response was, however, insufficient to induce the separation of the lowest two members of the homologous series of arylaliphatic acids.

It was found that short runs (20 cm.) by upward irrigation[8] gave the best results, since longer runs suffered from marked diffusion. Occasional fading of the background to assume the acid colour of the indicator on spraying is probably due to the presence of carbon dioxide from the dissociation of the carbonate buffer during the drying process, and a minimum drying period of 4–5 min. at 150° C. is necessary. There was no variation of R_F value with concentration over the range 0·2–1·2 per cent w/v. Concentrations greater than this gave such elongated spots that it was impossible to determine the R_F, an observation which is in agreement with that of Brown for salts of the aliphatic acids.

Selection of a satisfactory indicator was also investigated. The best results were obtained with buffered solutions of methyl red. A mixture of 5 parts of 0·1 per cent alcoholic methyl red solution with 10 parts of $M/15$ phosphate buffer solution pH 7·0 gave pink spots on a yellow background. The latter fades slowly to a very pale pink or disappears completely, leaving the spots still distinct. A mixture of equal portions of methyl red and bromo phenol blue (0·1 per cent alcoholic solutions) with twice the volume of buffer gave bright pink spots on a pale grey background, fading overnight to a pale violet. Benzoic and mandelic acids showed up better with this indicator mixture than with any of the other mixtures tried.

Ferric-ion Catalysed Decomposition of Hydrogen Peroxide and the Polymerization of Acrylonitrile

THE question of the mechanism of the iron (III) ion catalysed decomposition of hydrogen peroxide has been discussed in two recent communications[1]. The formation of free radicals initiating the polymerization of monomers during reaction between iron (II) ion and hydrogen peroxide has been demonstrated by Baxendale, Evans and Park[2], and the mechanism of the reaction of iron (II) ion and iron (III) ion with hydrogen peroxide has been discussed by Barb, Baxendale, George and Hargrave[3].

To clarify the question of the formation of free radicals in the iron (III) ion catalysed decomposition of hydrogen peroxide, I used water solutions of acrylonitrile (from the American Cyanamid Co., redistilled before use). The amount of hydrogen peroxide decomposed and that of polymer formed were determined during the course of the reaction. All other conditions remaining unchanged, the velocity of the decomposition of hydrogen peroxide in the presence of acrylonitrile is much slower than without it. The velocity of decomposition depends on the concentration of acrylonitrile. As an example, in a reaction mixture at 25·00 ± 0·05° C. which was 8·00 millimolar in iron (III) nitrate, 0·100 molar in hydrogen peroxide, and contained nitric acid so that the pH of the solution was 1·68 and was 0·40 molar in respect of acrylonitrile, the first-order reaction constant of hydrogen peroxide decomposition was $5{\cdot}5 \times 10^{-4}$ min.$^{-1}$, while without acrylonitrile the corresponding constant was $3{\cdot}1 \times 10^{-2}$ min.$^{-1}$. (The reaction constants were calculated analytically using the method of least squares.) The decomposition of the hydrogen peroxide was thus slowed down 56-fold. In the presence of acrylonitrile in the above case, the concentration of hydrogen peroxide was followed for 450 min., at which time about 22 per cent of the original hydrogen peroxide was used up. At the same time, 86 per cent of the monomer originally present was precipitated as an insoluble polymer. The velocity of formation of the polymer, after an initial induction period of about six minutes, during which time the solution remained clear to the eye, goes through a not very pronounced maximum. The maximum occurred between 30 and 40 min., from the appearance of the heterogeneity in the solution; the rate of the disappearance of the monomer was then $3{\cdot}7 \times 10^{-3}$ mol. min.$^{-1}$ lit.$^{-1}$. The ratio of disappearing monomer to that of hydrogen peroxide at the above maximum (expressed as molar ratio) is about 70.

At practically the same pH of the solution, but with the concentration of the monomer increased to 1·06 mol. lit.$^{-1}$ and that of hydrogen peroxide decreased to 0·021 mol. lit.$^{-1}$, the constant for the first-order decomposition of hydrogen peroxide was decreased only 17-fold compared with a monomer-free solution. The maximum velocity of monomer disappearance as measured by polymer formation was $2{\cdot}1 \times 10^{-2}$ mol. min.$^{-1}$ lit.$^{-1}$, and the ratio of disappearing monomer to that of hydrogen peroxide was then about 560. The formation of the polymer proceeds with easily determinable velocity even in the presence of hydrogen peroxide having a concentration of 1·8 millimoles lit.$^{-1}$.

The increasing acidity of the solution decreases the rate of formation of the polymer; it also decreases the rate of decomposition of hydrogen peroxide in the presence of the monomer.

These results extracted from the experimental data can only be interpreted in favour of the chain mechanism of the hydrogen-peroxide decomposition.

Hitherto, the amount of hydrogen peroxide which decomposed in the presence of a monomer with the formation of oxygen has not been determined. The molecular weight of the polyacrylonitrile formed has not been determined. It seems probable that such determination would be possible after polyacrylonitrile is transformed into polyacrylic acid by careful hydrolysis.

A detailed report and analysis of the results will be published in due course.

Acid Front in Granitization

DURING the course of field mapping a part of the khondalitic region near Salur (lat. 18° 36′ N., long. 83° 11′ E.) in the Vishakapatnam hill tracts, an interesting contact has been observed between a lens-like band of quartz-biotite-granulite (a member of the khondalites) and a porphyritic granite considered as intrusive[1] into the members of the khondalites in this region. The lens measures about 50 ft. in length, and 10 ft. in width, and appears at first sight as a caught-up xenolith amid the porphyritic granites.

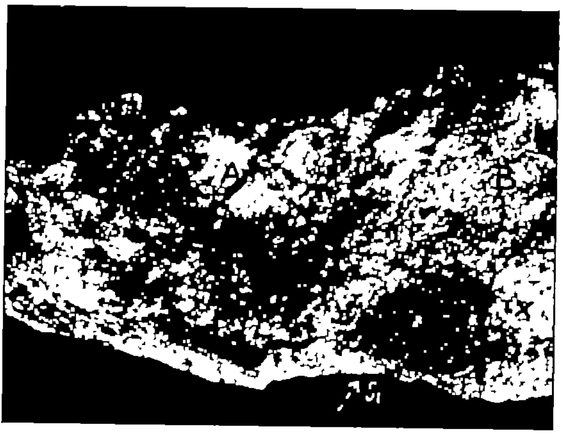

Fig. 1

Careful examination at the contact shows a profound transfusion of quartzo-feldspathic material from the porphyritic granite into the lens along the whole of its length up to a distance of 2 ft. A typical specimen was collected from the contact, and though unfortunately broken into two pieces in the field, it has in no way affected the features exhibited before the mishap.

The whole specimen can be divided into three well-defined zones, *A*, *B* and *C*, as shown in Figs. 1 and 2, which are easily distinguishable from one another to the naked eye by their colour, texture and grain size. Zone *A* belongs to the porphyritic granite, and zones *B* and *C* are those of the lens, adjacent to the granite. Zone *A*, white to greyish-white in colour (sometimes appears black due to streaks of biotite), consists of porphyritic feldspars measuring from two inches to eight inches, embedded in a coarse-grained matrix of quartz, feldspar, garnet and streaks of flaky biotite. Zone *B* is grey in colour, medium- to coarse-grained with quartz, feldspar and relatively tiny flakes of biotite. This zone shows often a tendency to the development of incipient feldspars (marked *X* in Fig. 1). Zone *C* is dark grey to bluish-grey, with fine grains of quartz-feldspar, biotite and grains of garnet.

An interesting feature in the specimen is the recognition of two quartzo-feldspathic screens (S_1 and S_2), consisting entirely of coarse quartz and feldspar grains to the exclusion of biotite and garnet, separating zone *A* from *B* and zone *B* from *C* respectively. The width of the screens varies from 3 mm. at its narrowest to 6 mm. at its widest points. Screen S_1 between zones *A* and *B* sometimes diffuses apparently into a porphyritic feldspar of zone *A*. Moreover, the two screens have slightly diffuse margins towards their preceding zones and clearly defined margins towards their forward zones. Such an occurrence of two distinct quartzo-feldspathic screens approximately parallel to one another precludes the possibility of considering them as chilled margins of the porphyritic granite against the lens, or as reaction rims developed as a consequence of reciprocal reaction between the porphyritic granite and the lens or as segregated veins due to metamorphic differentiation. Transfusion of matter from one solid into another under the influence of heat has been reported from an accidental experiment between two magnesite bricks in a furnace by Adams[2], and hence the development of zones in the lens has to be attributed either to solid diffusion or to transfusion of matter from the porphyritic granite into the lens under the influence of PTX conditions.

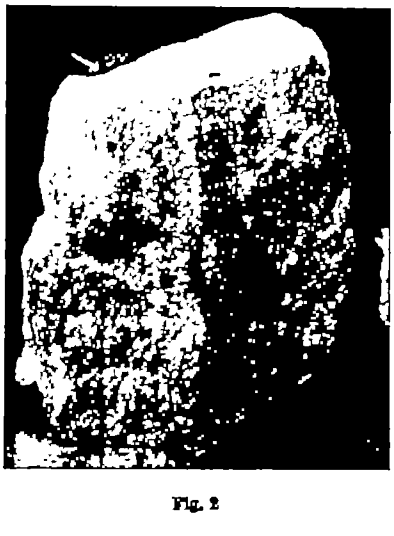

Fig. 2

The existence of "acid and basic fronts in granitization", due to the diffusion of ions of potassium, sodium, aluminium, calcium, magnesium, iron, titanium, phosphorus and silicon through paths of least resistance and obstruction in crystal lattices and along inter-mineral boundaries, has been accepted by the exponents of granitization[3-6]; hence the two quartzo-feldspathic screens may be regarded on the evidence adduced above as 'two acid fronts' advancing as waves either independently or following a basic front in the process of granitization of the lens.

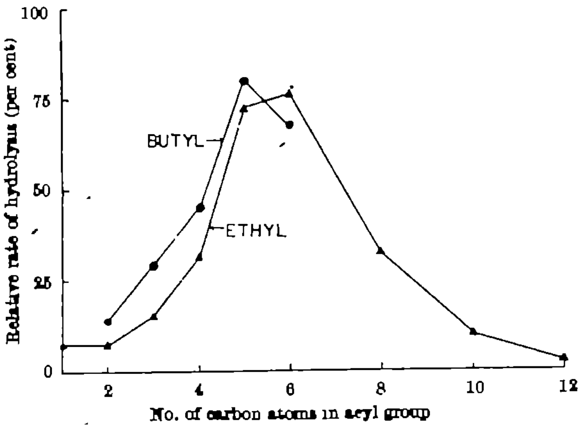
Ali-esterase of Rabbit Polymorphonuclear Leucocytes

Recently, Sturge and Whittaker[1] reported on the relative rates of hydrolysis of a series of straight-chain aliphatic esters by the aliphatic esterase (ali-esterase of Richter and Croft[2]) of horse plasma. With several notable exceptions, acetates were hydrolysed more rapidly than the corresponding propionate or *n*-butyrate (that is, the optimal number of carbon atoms in the *n*-acyl group was usually two) and *n*-butyl esters were hydrolysed more rapidly than the corresponding *n*-propyl or *n*-amyl esters (that is, the optimal number of carbon atoms in the *n*-alkyl group was usually four).

One of the difficulties encountered in studying the substrate specificity of an ali-esterase is that animal tissues contain at least four enzymes, or groups of enzymes, capable of hydrolysing the ester linkage of the simple aliphatic esters, namely, true cholinesterase (specific, *e*-type or aceto-cholinesterase), pseudo-cholinesterase (non-specific, *s*-type or butyro-cholinsterase), ali-esterase (common esterase) and lipase. Most tissue extracts, tissue homogenates or sera contain at least three, and may contain all four, of these nzymes, and there is considerable overlapping in heir substrate specificity.

Using the soluble ali-esterase preparation obtained rom rabbit polymorphonuclear leucocytes (Rossiter and Wong[3]), a study has been made of the relative ates of hydrolysis of a series of straight-chain aliphatic esters similar to that used by Sturge and Whittaker[1]. This enzyme preparation catalyses the hydrolysis of many aliphatic esters; but is inactive owards acetylcholine, acetyl-β-methylcholine, benzoylcholine and triolein. It is thus devoid of true cholinesterase, pseudo-cholinesterase or lipase activity and is a favourable preparation for the study of the substrate specificity of a typical ali-esterase.



Effect of changing the number of carbon atoms in the *n*-acyl group on the relative rate of hydrolysis of a series of ethyl and *n*-butyl esters by the ali-esterase of rabbit polymorphonuclear leucocytes. 100 per cent, rate of hydrolysis of methyl caproate

The accompanying figure shows the effect of increasing the number of carbon atoms in the *n*-acyl group on the relative rates of hydrolysis of a series of ethyl and *n*-butyl esters. Results are expressed as a percentage of the rate of hydrolysis of methyl caproate, which was the most rapidly hydrolysed straight-chain ester. In the two series presented, the most rapidly hydrolysed esters were ethyl *n*-caproate and *n*-butyl *n*-valerate, respectively; that is, the optimal number of carbon atoms in the *n*-acyl group was either five or six. Similar results were obtained with the methyl (peak at caproate), *n*-propyl and *n*-amyl (peak at valerate) esters. Changes in the size of the *n*-alkyl radical had only a slight effect on the rate of hydrolysis, methyl esters usually being the most rapidly hydrolysed. This pattern of specificity obviously differs greatly from that described by Sturge and Whittaker[1] for the horse plasma ali-esterase. The two sets of observations taken together would suggest that there are at least two groups of ali-esterases, each with a characteristic specificity pattern. Sturge and Whittaker[1] mention the possibility that their preparation may contain a second ali-esterase with a different pattern of specificity. The same could well apply to the rabbit polymorphonuclear leucocyte ali-esterase preparation. Limitation of material has precluded any attempts at enzyme purification. No special claims are made for the homogeneity of the preparation other than its freedom from cholinesterase and lipases.

Renewal of Bone Phosphate in Experimental Hyperparathyroidism

THE mode of action of parathyroid hormone is still obscure. The hormone seems, however, to exert its effect on calcium metabolism partly by a direct action on the bones[1]. Within a few hours profound changes appear in the bones of animals which have been given large doses of parathyroid extract[2]. The bone cells change their appearance and become de-differentiated, that is, they do not reach full maturity functionally[3]. Concurrently there is a rapid resorption of mineral salts, the resorbed bone being replaced by fibrous tissue.

Experiments, involving the use of radioactive phosphate (to be published in full elsewhere), have shown that the inorganic part of bone consists of different fractions with varying solubility in salt solutions, the fractions having different rates of renewal. The portion which is extractable with saturated ammonium sulphate of *p*H 7·5 has the highest exchange velocity with serum phosphate; the rest of the bone phosphate remains weakly labelled for long periods. Neither of these two fractions is homogeneous, however, each consisting of an unknown number of fractions with different rate of renewal. According to radioautographic and microradiographic investigations[4,5], the largest part of the radioactive phosphate taken up by the skeleton is deposited in the Haversian systems (osteons) with relatively low content of mineral salts, that is, young osteons[5], which thus also contain the portion of mineral salts soluble in saturated ammonium sulphate.

The present communication deals with experiments performed in order to obtain information concerning the age and structure of bone resorbed in chronic hyperparathyroidism. For that reason we have determined the ratio between the ammonium sulphate fraction and the remaining fraction, and the renewal in each of them, in rats submitted to prolonged administration of parathyroid hormone

Litter-mate male rats, about three months old, and placed on an optimal diet[6] containing 1 per cent calcium and with a Ca/P ratio of 1·0, have been used. Hyperparathyroidism was produced by giving the animals 'Para-thor-mone' (Lilly Co., Indiana) in increasing doses for twenty days; altogether 800 units were given to each animal. The last dose (100 units) was given two hours before administration of radioactive phosphate; 0·3 mC. radioactive phosphate was injected intraperitoneally. After the lapse of the desired time interval, the animals were sacrificed by decapitation. Blood was collected from the carotid arteries and immediately deproteinized in an equal volume of ice-cold 15 per cent trichloracetic acid. The specific activity (that is, number of impulses/μgm. phosphorus) of orthophosphate was then determined directly[7]. Bone samples (femur and tibia) were removed immediately after death, epiphyseal and diaphyseal bone being separated. The samples were frozen with solid carbon dioxide and pulverized in the frozen state. The powder obtained (about 100 mgm.) was extracted with 2 ml. of saturated ammonium sulphate in the presence of quartz sand for about twenty minutes with the aid of a high-speed rotating glass rod driven by compressed air. After filtering and washings, the residue was extracted with 15 per cent trichloracetic acid.

Table 1. RELATIVE SPECIFIC ACTIVITY OF PHOSPHATE IN TWO DIFFERENT FRACTIONS OF MINERAL SALTS IN EPIPHYSEAL AND DIAPHYSEAL BONE IN NORMAL AND HYPERPARATHYROID RATS

Specific activity of orthophosphate in blood = 100. Phosphate was determined by the method of Fiske and SubbaRow[8]. Radioactivity was measured under a counter after drying an aliquot of the extract on an aluminium dish

Time in hours	1·5		3·0	
Kind of sample	Control animal	Treated animal	Control animal	Treated animal
Epiphyseal bone				
Ammon. sulphate fraction	43	9·9	40	21
Remainder	6·0	1·3	5·4	3·6
Diaphyseal bone				
Ammon. sulphate fraction	15	2·7	22	6·9
Remainder	2·1	0·27	2·1	0·72

Table 1 shows the specific activity of the two fractions of bone salts in relation to that of orthophosphate in the blood. It is clearly demonstrated that, as a consequence of the treatment with high doses of parathyroid hormone, the renewal of phosphate becomes, after the lapse of 1·5 hr., much less both in epiphyseal and diaphyseal bone. The relative lowering of the renewal rate seems to be the same in both fractions. In the experiment of 3-hr. duration, the relative specific activity of the two fractions of bone minerals is in the control animal about the same as after 1·5 hr., which is in agreement with other reports[9,10]. In the treated animals, however, there is a continuous rise in the relative specific activity in the two fractions, both in epiphyseal and diaphyseal bone.

Table 2. RELATIVE AMOUNT OF TWO FRACTIONS OF PHOSPHATE IN EPIPHYSEAL AND DIAPHYSEAL BONE IN NORMAL AND HYPERPARATHYROID RATS*

Fraction	Epiphyseal bone		Diaphyseal bone	
	Control animal	Treated animal	Control animal	Treated animal
	Per cent	Per cent	Per cent	Per cent
Ammon. sulphate	21	19	16	15
Remainder	79	81	84	85

* Each value represents the mean of two determinations.

Table 2 shows that the ratio between the two fractions of bone salts is the same in control animals as in those treated with parathyroid hormone. These results thus indicate that, in hyperparathyroidism, both fractions are resorbed to the same degree, that is, there is the same destruction in young osteons as in old bone.

Because of the variety of mineral salts resorbed, the hypothesis is advanced that the primary action of parathyroid hormone on bone is more intimately associated with the organic constituent of the bone tissue than with the mineral salts. At the same time the difference in the rate of renewal of phosphate in the skeleton between normal animals and thos treated with parathyroid hormone seems to suppor the view that the rate of renewal is not only dependen upon simple physical conditions such as the solubilit of the mineral salts or degree of vascularization calcification as well as rate of renewal must be th result of specific cell activity, which may be regulate by hormonal control.

Composition of Histone prepared from Rat Liver Deoxypentosenucleoprotein

THE recent report[1] by Hamer on the amino-aci composition of calf thymus histone prompts us to communicate some corresponding observations on histone prepared from rat liver deoxypentosenucleoprotein. Nuclei were isolated from briefly homogenized suspensions of perfused rat liver (Sprague-Dawley–Holtzmann strain) and washed four times A citric acid technique at pH 6·1 was employed i the preparation[2]. The nuclei were subjected t differential extraction with sodium chloride, 1·0 M salt being used for the extraction of the deoxypentosenucleoprotein and dilution to 0·14 M salt fo its precipitation. Unlike the preparations describe in the literature, these are non-fibrous on precipitation, readily soluble in water, non-viscous in eithe water or molar sodium chloride solution, and of lo molecular weight. The deoxypentosenucleoprotei was dialysed against water and the solution s obtained was lyophilized.

Histone was prepared from such stock preparation of deoxypentosenucleoprotein. 300 mgm. was treate with 0·25 N hydrochloric acid at 2°–3° for half a hour. The histone derived from the resultan splitting of the deoxypentosenucleoprotein was salte out by saturation with sodium chloride. The histon was dissolved in water and, after exhaustive dialysi against water, the solution was lyophilized.

When a comparable preparation from calf liver wa examined in the analytical ultracentrifuge (Spinc Model E) at a concentration of 1 per cent and pH 3·8 in water, it showed a single symmetrical boundar throughout the period of sedimentation. Homogeneity was also shown in a similar run (1 per cen solution in 0·2 M sodium chloride) at pH 4·7.

For determination of the amino-acid composition a sample of 38·6 mgm. was hydrolysed with 200 part

Effect of a Single Injection of Carbon Tetrachloride upon the Activity of the Pseudo-cholinesterase in the Liver and Serum of Male and Female Rats

Brauer and Root[1] and Ellis, Sanders and Bodansky[2] produced liver injury in rats by frequent injections of small doses of carbon tetrachloride over a period of six to twelve days. There was a definite fall in the cholinesterase activity of the liver and a somewhat delayed fall in that of the serum; but the continued administration of the poison renders the findings difficult to interpret. If the enzyme in the serum is derived from the liver[1,2], the regeneration of the liver tissue after injury should be accompanied by restoration of the serum and liver cholinesterase to the normal level. Cameron and Karunaratne[3] found in the rat that a large single injection of carbon tetrachloride caused zonal necrosis, centrilobular in distribution, within twenty-four hours, and that recovery was complete in seven to fourteen days. It was therefore decided to follow the serum and liver cholinesterase activity in male and female rats for eleven days after a single subcutaneous injection of 0·25 ml. carbon tetrachloride (B.D.H. Analar)/100 gm. body-weight.

Forty-two black-and-white hooded rats of each sex were divided into groups of seven, and the experimental procedures for sampling and estimating the pseudo-cholinesterase in the liver and in the serum were the same as in an earlier study of the effect of starvation[4]. The mean weights of the male and female rats were 295 gm. and 200 gm., respectively, and they changed little during the experiments. Histological sections of the liver were kindly prepared for us by Dr. A. M. Barrett (Department of Pathology, Cambridge). Within 24 hr., small areas of necrosis had developed in the centres of the liver lobules of most of the animals of both sexes; but by the eleventh day the livers again appeared almost or quite normal.

Effect of a Single Subcutaneous Injection of 0·25 ml. Carbon Tetrachloride/100 gm. Body-weight on the Pseudo-cholinesterase Activity of the Liver and Serum of Male and Female Rats

Sex	Days after injection	Liver		Serum
		Weight (gm./100 gm. initial body-weight. ± Stand. dev.)	Cholinesterase units/gm. liver	Cholinesterase units/ml. serum
Male	0	3·18 ± 0·22	40	8·3
	1	3·62 ± 0·32	17	6·5
	3	3·42 ± 0·33	20	6·7
	5	3·70 ± 0·32	24	5·9
	7	3·89 ± 0·40	33	7·3
	11	3·43 ± 0·31	35	6·4
Female	0	3·00 ± 0·27	117	32
	1	3·60 ± 0·26	32	29
	3	3·82 ± 0·39	65	22
	5	3·82 ± 0·63	75	21
	7	3·85 ± 0·47	78	18
	11	3·58 ± 0·44	95	36

The unit of cholinesterase is defined as the amount of enzyme which liberated 1 µl. carbon dioxide/min. from acetylcholine under standard conditions.

From the accompanying table it will be seen that the cholinesterase activities of the liver and serum of female rats were initially much greater than those of the males. In the females, within 24 hr. after the injection, the liver cholinesterase had dropped to a quarter of its initial value, but by the eleventh day it had risen again almost to its original level. The activity of the serum fell more slowly, and was still falling some days after the activity of the liver had begun to rise; but by the end of the experiment it also had returned to normal. A similar delay in the fall of the serum cholinesterase was observed during starvation, for whereas the liver cholinesterase dropped rapidly during the first two days, the serum enzyme decreased gradually throughout a six-day fast[4].

In the male rats, carbon tetrachloride caused a much smaller fall in the cholinesterase activity of the liver, followed by recovery almost to the normal level in seven to eleven days, whereas the serum cholinesterase remained within the normal limits. During starvation[4], there was no appreciable change in the cholinesterase activities either of the serum or of the liver.

It appears, therefore, that in the female rat a large fall or rise in the cholinesterase activity of the liver is followed by a corresponding change in that of the serum. The close association between the histological recovery of the liver, and the restoration first of the liver and then of the serum cholinesterase activity to normal values, confirm the hypothesis that the liver is the source of most of, or all, the serum enzyme in the rat. The absence of a definite fall in the serum activity following liver injury in the male rats suggests that either the changes in the activity of the liver after carbon tetrachloride were not sufficiently great to be reflected in the serum, or alternatively that the 'non-labile' liver enzyme[4] is not the source of the small amount of pseudo-cholinesterase in the serum of the male rat.

Histological Changes in the Epithelium of the Small Intestine during Protein Absorption in the New-born Animal

The absorption, without change, of certain globulins of the colostrum by the new-born animal has been known for many years[1]. Smith[2] has reported that the epithelial cells of the ileum of calves contain feebly staining homogeneous bodies which are present in late intra-uterine life but largely disappear within three days of birth. Other intracellular bodies, apparently protein in nature, have been described in the intestinal epithelium of suckling mice and compared with the meconium corpuscles of the human fœtus[3].

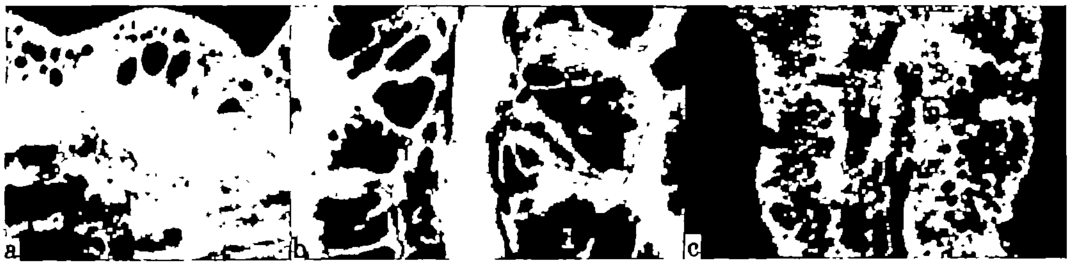
Recent experiments in which the absorption of colostrum globulins was examined in young calves[4] provided material for a study of the changes in the intestinal epithelium under controlled experimental conditions. Colostrum whey, from which the fat had been removed, was introduced through a duodenal cannula. Pieces of the small intestine were removed from the anæsthetized animals and immediately placed in either 10 per cent formol-saline or Susa. Samples were taken from calves 3–24 hr. after birth, which were absorbing the colostrum globulins, and from others of a similar age to which whey had not been administered, and from calves, aged 63–65 hr.

The epithelium of the ileum of calves 9–36 hr. old contained the vesicles described by Smith[2], which stained lightly with toluidine blue.

A striking change was found in the intestinal epithelial cells of calves in which the absorption of protein was taking place. Any whey remaining in the lumen of the gut was coagulated by the fixative and stained as a homogeneous mass with iron hæmatoxylin, azocarmine, eosin or orange *G*. Globules with similar staining properties to the protein of the whey were present in the majority of the intestinal epithelial cells of the jejunum and ileum. In some sections material with the same staining reactions as the whey could be seen in the lacteals. Only a very few droplets of colostrum protein were observed within the cells when the whey was given to calves 63–65 hr. after birth. This is in accordance with the much smaller absorption of globulins found in these older animals.

The size and situation within the cell of the globules of protein varied. In some sections discrete droplets up to 2 μ in diameter were present immediately within the lumen border of the epithelial cells (Fig. *a*). In addition to these, protein material was present in the cytoplasm of the epithelial cells either as one or two large globules, up to 10 μ in diameter, or as a number of smaller drops, 2 μ to about 6 μ in diameter (Figs. *a*, *b* and *c*). These variations resembled in some respects those reported in the distribution and size of intracellular fat droplets during the absorption of fat[5,6].

The observations suggest that, under the conditions of these experiments, the protein which was absorbed without change within the first 24–48 hr. after birth passed through the cells of the epithelium of the small intestine.



Intestinal epithelium of calves 3–24 hr. old, iron hæmatoxylin staining. (*a*) Ileum; (*b*) jejunum; and (*c*) ileum, from animals which received colostrum whey. Magnification 970

Chlorophyll Inhibition and Growth Regulation by Several Tetronic Acid Derivatives

It has been shown that coumarin derivatives are particularly active as inhibitors of germination and root-growth[1-3], and it has been suggested[4] that this action is at least partially due to the unsaturated lactone ring. Since other compounds, hexenolactone[5,6] and protoanemonin[7], containing this unsaturated lactone ring have clearly exhibited some influence on the growth of plants, it seemed interesting to test the simplest compounds having this structure. As an approach to this simple ring, several tetronic acid derivatives were selected which have been synthesized by J. Lecocq[8], to whom we are indebted for the supply of the samples tested.

These compounds were tested on germinating seeds and seedlings of Marketer variety of cucumber (*Cucumis melo*) and White Banner variety of wheat (*Triticum sativum*). The method was to germinate seeds in Petri dishes on filter paper containing the various tetronic acid derivatives at different concentrations. Twenty-five seeds were placed in each dish and 5 ml. of solution was added.

The tetronic acids which were tested included: 3-acetyl-5-methyl-tetronic acid, 3-(α-imino-ethyl)-tetronic acid, 5-5-diphenyl-tetronic acid, 3-(α-methyl-imino-ethyl)-5-phenyl-tetronic acid, 3-diazophenyl-tetronic acid, 3-3′-methylene-5-5-5′-5′-tetra-ethyl-bis-tetronic acid, 3-(α-imino-ethyl)-5-methyl-tetronic acid. A compound of similar configuration, the 2-imino-4-hydroxy-5-5-diphenyl-oxazole was also tested.

The compound producing the most interesting results was 3-(α-imino-ethyl)-5-methyl-tetronic acid. When cucumber seeds were germinated and grown in 100 p.p.m. of this compound, they produced large yellow cotyledons and etiolated hypocotyls. When these seedlings were transplanted into soil and placed on a greenhouse bench, they became white, resembling albino plants, and died after five or six days.

At concentrations greater than 100 p.p.m., not only did cucumber seedlings become chlorotic, but also hypocotyls were markedly inhibited in development. When wheat seeds were allowed to germinate and develop in a solution of 100 p.p.m. or more of 3-(α-imino-ethyl)-5-methyl-tetronic acid, they first germinated and grew normally, but after several days became yellow and then at last partially white. They failed to develop normally and after about two weeks died. When 1 ml. of a solution of 1,000 p.p.m. of 3-(α-imino-ethyl)-5-methyl-tetronic acid was injected into seedlings of red kidney bean stems at a point just below the heart-shaped leaves, the new growth which developed above the primary leaves was in many instances white and stunted. Also, when either of the primary leaves was dipped in a solution containing 1,000 p.p.m. of this compound, the leaf which was dipped became yellow and then gradually white at the margin, and finally about 85 per cent albino with some green colouring still present at the base of the blade.

The action of 2-imino-4-hydroxy-5-5-diphenyl-oxazole was in sharp contrast to that of the preceding compound. When a young primary leaf of red kidney bean was dipped in a solution containing 1,000 p.p.m., the expansion of the leaf was not only almost completely inhibited, but also the leaf became dark green in colour. A solution of 100 p.p.m. also greatly retarded germination of cucumber seeds and completely inhibited seedling development.

The other tetronic acids tested showed less striking effects. For example, responses from 3-(α-imino-ethyl)-tetronic acid were somewhat similar to those from 3-(α-imino-ethyl)-5-methyl-tetronic acid, but to a lesser degree. Preliminary tests with 3-acetyl-5-methyl-tetronic acid suggest that this compound actually stimulates seedling development in wheat.

New Hosts of *Phytophthora Infestans* in Kenya

The potato has been grown in Kenya for more than half a century, frequently under conditions of temperature and humidity favourable to blight epidemics. It was not, however, until 1941 that blight appeared, and in that year caused widespread destruction of the crop from the eastern escarpment of the Rift Valley, where the first outbreak was observed, to Mt. Kenya[1]. In the following year the disease occurred throughout the Highlands, reaching Tanganyika, Uganda and the Belgian Congo, and is now apparently endemic.

From 1943 blight-immune potatoes from Dr. W. Black have been grown extensively. Those received up to 1948 were immune from blight biotypes *A* and *C* and in the field showed complete immunity. A new biotype *B* which appeared in Tanganyika in 1946 reached Kenya in 1948 and resulted in the breakdown of this resistance, causing much disappointment among farmers. New hybrids immune from biotypes *A*, *B*, *C*, *E* and *F* are now under trial.

During 1950, the foliage of certain woody perennial species of *Solanum* were attacked by blight. In the Highlands of Kenya, these plants abound as weeds of waste places and pastures and as forest under-shrubs. No blight had been observed on them hitherto. The disease was first seen on *S. indicum*, growing in forest shade at 6,000 feet near Nairobi. A few weeks later it was collected on leaves of a *Solanum* species, near to *S. panduraeforme*, in forest clearings at the foot of Mt. Kenya some hundred miles to the north-east. A further search discovered *S. incanum*, one of the commonest species, to be generally attacked in the vicinity of the originally observed outbreak on *S. indicum*. (All plants were determined by P. J. Greenway, East African Herbarium.)

Sporangia from *S. incanum* readily infected an unknown variety of potato, from which plants the fungus was transferred to *S. indicum*. Tests by Dr. Black with cultures from this isolation indicated strain *C* as the biotype.

It would appear that a period of approximately ten years elapsed before the resistance of three of the indigenous *Solanum* species to this exotic fungus was broken down.

The occurrence of *P. infestans* on widely distributed perennial host plants may offer new scope for the evolution of yet more aggressive strains of the fungus.

Changes in Colour Sensitivity of the Eye with Posture

The colour sensitivity of the human eye appears to be influenced, among other factors, by the physical position of the observer.

Normally, when an observer is making colour comparisons, he is in the erect position and with normal vision both eyes exhibit similar colour sensitivities. I have observed, however, that if the observer is in the prone position lying on one side, a gradual difference between the colour response of the two eyes develops. After a few minutes the lower eye becomes markedly red-sensitive compared with the upper eye. If now the observer lies on his back, the two eyes gradually return to equality of colour response. By turning on to the opposite side, the eye formerly red-sensitive will be uppermost and will then gradually develop blue-sensitivity compared with the lower eye.

It occurred to me that this effect, which I have not seen mentioned elsewhere, may be of interest in connexion with theories of colour vision.

The Theory of Magnetic Storms and Auroras

In *Nature* of June 16, in a communication on the theory of magnetic storms and auroras, Prof. H. Alfvén emphasizes the need for the theorist to test his work by experiment. He and his colleagues have striven to follow this laudable maxim, which was also urged in his book[1], for example, on p. 37 regarding cosmic discharges, and on p. 78 regarding magneto-hydrodynamic waves (and a note added in proof records the success of S. Lundquist in experimentally demonstrating them). He gave (pp. 39–41) the scale relations between various physical magnitudes involved in laboratory experiments for illustrating large-scale natural phenomena, and these he discussed also (pp. 201–203) in relation to Malmfors's experiment intended to illustrate magnetic storm and auroral theory.

The difficulty is that it may be beyond present experimental powers to fulfil these scale relations in the laboratory—and Prof. Alfvén remarks (p. 201) that this is so regarding the magnetic field in Malmfors's experiment. I have myself recently proposed[2] another experiment to illustrate magnetic storm theory; the fulfilment of the scale relations involved will certainly be difficult, though apparently not impossible. Not having at my disposal experimental skill or facilities, I should much welcome the execution of the experiment by Prof. Alfvén and his colleagues.

Failing such experiments, a purely theoretical treatment, as Prof. Alfvén remarks (p. 37), though "certainly very precarious", is "still, in many cases, the only way of attack". Prof. Ferraro and I, in our work on magnetic storms[3], have often mentioned our consciousness of the precarious nature of such work, and Prof. Alfvén, in his summary and discussion[1] of his own theory[4], likewise very properly makes many reservations as to the proof of his conclusions and the need for the extension of his analytical treatment.

A theorist in such a field must select what he considers the initial bases for the theory, and then develop it from these premises as accurately as possible; mathematical difficulties may force him to stop his chain of deductions without having taken it as far as he would like, and also to leave some of the links weaker than he would wish. The choice of the initial bases may be partly a matter of dispute, and so may be the accuracy of the chain of reasoning from them.

Prof. Ferraro and I will welcome the publication of the objections to our theory that Prof. Alfvén believes are fatal to it, so that if they are invalid we may rebut them, or if valid, re-direct our efforts.

Prof. Cowling[5] has criticized the accuracy of the deductions made by Prof. Alfvén from his initial premises, and his criticisms have not yet received a satisfactory answer, though they are referred to in "Cosmical Electrodynamics", p. 200.

But the subject is far too intricate to be suitable for its details to be discussed in the correspondence columns of *Nature*.

FORTHCOMING EVENTS

(*Meeting marked with an asterisk * is open to the public*)

Monday, July 16

BRITISH SOCIETY FOR THE HISTORY OF SCIENCE (in the Lecture Theatre, Science Museum, Exhibition Road, London, S.W.7), at 4.45 p.m.—Dr. F. Sherwood Taylor: "The History of Science, 1851–1951".*

Monday, July 16—Saturday, July 21

DEPARTMENT OF SCIENTIFIC AND INDUSTRIAL RESEARCH (at the College of Aeronautics, Cranfield, Bedford).—Conference on "Automatic Control".

Tuesday, July 17

INSTITUTION OF CHEMICAL ENGINEERS (at the Royal Institution, 1 Albemarle Street, London, W.1), at 10 a.m.—Conference on "Mixing and Agitation in Liquid Media".

FAUNA PRESERVATION SOCIETY (at the Zoological Society of London, Regent's Park, London, N.W.8), at 4.15 p.m.—Mr. F. W. Champion: "Tropical Forests and Wild Life Conservation".

Wednesday, July 18

ROYAL SANITARY INSTITUTE (at 90 Buckingham Palace Road, London, S.W.1), at 11 a.m.—Conference on the Report of the Catering Trade Working Party on "Hygiene in Catering Establishments".

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Sir Harold Scott, K.C.M.G.: "Some British Contributions to Tropical Medicine".

ROYAL METEOROLOGICAL SOCIETY (at East Malling Research Station, East Malling, Maidstone).—Summer Meeting.

Thursday, July 19

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Prof. H. E. Shortt, F.R.S.: "The Life Cycle of the Malaria Parasite".

Friday, July 20

BIOMETRIC SOCIETY, BRITISH REGION (at the National Institute for Research in Dairying, Shinfield, Reading), at 11.30 a.m.—Tenth Meeting.

Saturday, July 21

BIOCHEMICAL SOCIETY (in the Department of Biochemistry, The University, Sheffield), at 10.30 a.m.—Scientific Papers.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

JUNIOR ASSISTANT PHYSICIST, mainly in connexion with radiotherapy—The Secretary, University College Hospital, Gower Street, London, W.C.1 (July 20).

ASSISTANT LECTURER (Grade A) IN PHYSICS—The Registrar, Nottingham and District Technical College, Shakespeare Street, Nottingham (July 21).

ASSISTANT WORKS CHEMIST (with a sound knowledge of the control of gas manufacture, and experienced in carrying out all the usual gas works tests)—The Divisional Manager, West Midlands Gas Board, Walsall and District Division, Walsall Factory Estate, Tame Bridge, West Bromwich Road, Walsall, quoting Ref. N. (July 21).

ASSISTANTS (Grade B) IN MATHEMATICS (knowledge and interest in statistics would be an asset), BIOLOGY (degree including zoology and botany with honours in one of these subjects), and CHEMISTRY (2 posts, *a*, research or industrial experience and some knowledge of biological subjects would be an advantage, *b*, to teach inorganic chemistry up to B.Sc. Special and A.R.I.C. standard and to assist in general chemistry up to B.Sc. General level)—The Principal, Derby Technical College, Normanton Road, Derby (July 21).

CHEMIST in the Executive's Laboratory Service, to be in immediate day-to-day charge of a power station laboratory in the N.W. or S.W. area of London—The Staff Officer (F/EV.180), London Transport Executive, 55 Broadway, London, S.W.1 (July 21).

GRADUATE with biological training, for work on soil bacteriology—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (July 21).

GRADUATES IN CHEMISTRY or PHYSICS for two Bursaries, to do research on flame propagation in gases—The Registrar, Imperial College of Science and Technology, South Kensington, London, S.W.7 (July 21).

PRINCIPAL OF THE WEDNESBURY COUNTY TECHNICAL COLLEGE—The Director of Education, Department F.E., County Education Offices, Stafford (July 21).

ASSISTANT LECTURER IN AGRICULTURAL ECONOMICS—The Registrar, The University, Leeds 2 (July 24).

LECTURER IN INORGANIC AND PHYSICAL CHEMISTRY, and a LECTURER IN ORGANIC CHEMISTRY—The Secretary and Registrar, University College of North Wales, Bangor (July 24).

PROFESSOR OF NAVAL ARCHITECTURE AND MARINE ENGINEERING, a PROFESSOR OF POWER STATIONS (Mechanical), and a PROFESSOR OF STRENGTH OF MATERIALS AND SANITARY ENGINEERING, at Farouk I University, Alexandria—The Director-General, Egyptian Education Bureau, 4 Chesterfield Gardens, London, W.1 (July 25).

PRINCIPAL SCIENTIFIC OFFICER (with a first- or second-class honours degree, preferably in engineering, and some industrial and research experience) in the Mechanical Engineering Research Organization of the Department of Scientific and Industrial Research, to develop and initiate research into mechanisms for application to mechanical engineering problems—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting No. S.4041/51 (July 26).

LECTURER IN ENGINEERING—The Secretary, The University, Aberdeen (July 27).

COMPUTER (Scientific Technologist III) at headquarters Scientific Department (Scientific Control)—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/351 (July 28).

EXPERT DESIGNING ENGINEER under the Government of India, in India, to be responsible to the Chairman, Central Waterpower, Irrigation and Navigation Commission, for the mechanical and electrical design of such transmission systems as will be required for grid supply connecting super-hydro power stations and long-distance power transmission projects—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London; W.C.2, quoting D.280/51A.O. (July 28).

MECHANICAL ENGINEERS (Scientific Officer grade) at the Ministry of Supply headquarters in London, to originate and supervise research associated with mechanical engineering problems in the aero-engine industry and to represent the Ministry in committee work—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting C.340/51A (July 28).

MECHANICAL ENGINEERS (Scientific Officer grade) at the Royal Aircraft Establishment, for research into the more fundamental aspects of the development of aircraft hydraulics, pneumatic and oxygen systems, involving problems of gas and liquid flow, control systems and storage—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting C.354/51A (July 28).

SENIOR LECTURER IN ANTHROPOLOGY at the Australian School of Pacific Administration, Mosman, Sydney, and an ANTHROPOLOGIST (male) in the Public Service of Papua and New Guinea—The Official Secretary, Australian High Commissioner's Office, Strand, London, W.C.2, quoting 'Department of Territories, Canberra' (July 28).

TEMPORARY ASSISTANT TECHNICAL EXAMINING OFFICER (male) in the Victualling Department of the Admiralty—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.60/51A (July 28).

ASSISTANT IN THE DEPARTMENT OF BOTANY, University College, Dundee—The Secretary, The University, St. Andrews (July 31).

CHIEF AGRICULTURAL ECONOMIST (with a specialized degree in agricultural economics, and practical experience in the marketing of agricultural products and in investigations dealing with the costs of production of these products) in the Department of Agriculture and Lands, Southern Rhodesia—The Secretary, Office of the High Commissioner for Southern Rhodesia, 429 Strand, London, W.C.2 (July 31).

DEMONSTRATOR IN GEOGRAPHY—The Secretary, The University, 38 North Bailey, Durham (July 31).

ENGINEERS (Principal Scientific Officer grade) at the London headquarters of the Ministry of Supply. (Ref. C.355/51A) to take charge of a section responsible for initiation and co-ordination of research and development work on aircraft pressure cabins and associated problems and equipments; (Ref. C.356/51A) to control a section responsible for co-ordinating investigations with mechanical engineering problems in connexion with aircraft development—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (July 31).

JUNIOR PROFESSIONAL OFFICERS (2) IN THE ENTOMOLOGICAL BRANCH, Department of Agriculture, Southern Rhodesia—The Secretary, Office of the High Commissioner for Southern Rhodesia, 429 Strand, London, W.C.2 (July 31).

LECTURER IN PURE MATHEMATICS—The Registrar, King's College, Newcastle-upon-Tyne (July 31).

LECTURER or ASSISTANT LECTURER IN AGRICULTURAL ECONOMICS at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (July 31).

METALLURGIST (Chemist III grade) for the Ministry of Supply in Middlesex, to take charge of metallographic laboratories—work covers metallic materials of all kinds used in aircraft, with joining, corrosion preventive and other processes applied to metals—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.440/51A (July 31)

PHYSICISTS and PHYSICAL CHEMISTS (Experimental Officer grade) at a Ministry of Supply research and development establishment near London, to operate an electron microscope and to assist in X-ray crystallographic work—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting A.180/51A (July 31).

RESEARCH FELLOW IN ANTHROPOLOGY at the West African Institute of Social and Economic Research, University College, Ibadan—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (July 31).

SCIENTIFIC ASSISTANT (university graduate in science or agriculture, preferably with special training in nutrition and/or knowledge of foreign languages)—The Director, Rowett Research Institute, Bucksburn, Aberdeenshire (July 31).

SENIOR PRINCIPAL SCIENTIFIC OFFICER (with a first- or second-class honours degree in some branch of science or engineering, or an equivalent qualification, and good experience in research is essential) in the Building Operations Research Unit of the Building Research Station (Department of Scientific and Industrial Research)—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4042/51 (August 2).

CHAIR OF PHYSICS in the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth 5 Gordon Square, London, W.C.1 (August 4).

GRADUATE IN PHYSICS (with a bias towards engineering) to undertake research work in the unexplored field of glasshouse heating and ventilation—The Head of the Garden Research Department, John Innes Horticultural Institution, Bayfordbury, Hertford (August 4).

RESEARCH OFFICER (Biologist), DIVISION OF FISHERIES, to take part in the research programme on pearl-shell culture at Thursday Island—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 3282 (August 4).

CHEMISTS (Principal Scientific Officer or Senior Scientific Officer grade) at the Atomic Energy Research Establishment, Harwell, for work on the electro-magnetic method of separation of stable isotopes—The Secretary, Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting No. S.4045/51 (August 8).

MECHANICAL ENGINEER (Principal Scientific Officer grade) with considerable design experience, to study and to solve the special problems connected with the design of modern radar aerials and their associated scanning and rotating mechanics, an ENGINEER (Principal Scientific Officer grade) with wide experience in, and complete responsibility for, the successful engineering of complex projects involving many different specialist component parts both electrical and mechanical, an ELECTRONICS ENGINEER (Principal Scientific Officer grade) with outstanding ability in precision designs associated with complex electronic equipment, an ENGINEER (Principal Scientific Officer grade) with high-grade experience of the theory, design and utilization of servo-mechanisms, at an Admiralty establishment in the south of England; MECHANICAL ENGINEERS (Principal Scientific Officer grade) with considerable experience in the design of intricate mechanisms, at an Admiralty establishment in the Home Counties; PHYSICIST or ELECTRONICS ENGINEER (Senior Scientific Officer or Principal Scientific Officer grade) with an excellent theoretical understanding and practical experience of, and responsibility for, the design and development of electronic circuits, especially in the high and medium frequency bands, at an Admiralty establishment in the Home Counties; STRUCTURAL ENGINEER with a first- or second-class honours degree in Engineering, or a MATHEMATICIAN with an honours degree in Mathematics (Principal Scientific Officer grade) to supervise the work of applied mathematicians and engineers in the Structural Mechanics Division, at an Admiralty establishment at Rosyth—The Secretary, Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting No. S.4043/51 (August 9).

ASSISTANT IN THE STATISTICS SECTION, for work on problems of tree variation and measurement—The Secretary, East Malling Research Station, Maidstone, Kent (August 11).

LECTURER IN PHYSICS (preferably in Experimental Physics) at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (August 15).

SENIOR SCIENTIFIC OFFICERS (with a first- or second-class honours degree in botany, and well qualified in systematic botany), for research work in the Herbarium or Laboratories, supervision of staff, the identification of plants and plant products and the control of Laboratory equipment, at the Royal Botanic Gardens, Edinburgh—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting No. S.4046/51 (August 16).

SENIOR LECTURER IN FLUID MECHANICS AND HYDRAULICS, and a LECTURER IN CIVIL ENGINEERING, at Canterbury University College, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (August 20).

LECTURER IN GEOGRAPHY—The Secretary, The University, 36 North Bailey, Durham (August 31).

CHAIR OF ANATOMY in the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (September 1).

RESEARCH ASSISTANTSHIP IN INDUSTRIAL RELATIONS—The Registrar, University College of South Wales, Cathays Park, Cardiff (September 10).

ASSISTANT CIVIL ENGINEERS in the Department of Drainage and Irrigation, Malaya—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting No. 27329/24.

ASSISTANT ENGINEER with power plant experience (and experience in the running and maintenance of diesel-driven A.C. generators, the upkeep of A.C. motors, switchgear and cables) to the Sudan Gezira Board—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Sudan Gezira Board, Power Plant 4/292'.

ASSISTANT LECTURER AND DEMONSTRATOR (with a sound scientific knowledge; a knowledge of leather manufacture would be an advantage)—The Principal, Leathersellers' Technical College, 176 Tower Bridge Road, London, S.E.1.

ASSISTANT LECTURER (temporary) IN PHILOSOPHY—The Registrar, University College, Singleton Park, Swansea

CHEMICAL ENGINEER or CHEMIST with production experience, for oil plant at Wick, north Scotland—The Herring Industry Board, 1 Glenfinlas Street, Edinburgh 3.

DEPARTMENTAL ASSISTANT (university graduate, preferably with special qualifications in agricultural chemistry) IN AGRICULTURAL CHEMISTRY, and a DEPARTMENTAL ASSISTANT IN POULTRY HUSBANDRY, at the School of Agriculture, Sutton Bonington—The Registrar, The University, Nottingham.

DIRECTOR (Senior Principal Scientific Officer grade) OF THE WEST AFRICAN BUILDING RESEARCH ORGANIZATION—The Under-Secretary of State, Colonial Office, Research Department, Sanctuary Buildings, Great Smith Street, London, S.W.1.

EXECUTIVE ENGINEER IN THE PUBLIC WORKS DEPARTMENT, British Honduras—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting No. 27322/138.

HONOURS GRADUATE (Scientific Officer grade) for research on methods of microbiological assay of vitamins and amino-acids—The Secretary, Rowett Research Institute, Bucksburn, Aberdeenshire.

LECTURER (university graduate with an honours degree in engineering or physics) IN REFRIGERATION, and a LECTURER (with a degree in mechanical engineering and some practical experience of fan applic tion) IN FAN ENGINEERING—The Clerk to the Governors, Nation College for Heating, Ventilating, Refrigeration and Fan Engineeri Borough Polytechnic, Borough Road, London, S.E.1.

LECTURER IN INORGANIC CHEMISTRY (including spectrochemic analysis), a LECTURER IN APPLIED MATHEMATICS, a LECTURER PHYSICS, and a LECTURER IN ZOOLOGY—The Principal, Sir John Ca College, Jewry Street, London, E.C.3.

LECTURER IN POULTRY SCIENCE—The Bursar, Harper Adar Agricultural College, Newport, Shropshire.

LECTURER or Grade B ASSISTANT IN PHYSICS—The Registr Medway Technical College, Gardiner Street, Gillingham, Kent.

MATHEMATICIAN or MATHEMATICAL PHYSICIST (with a good honou degree and, preferably, some knowledge of the theory of elasticit for research in applied mechanics—The Personnel Officer, British Ir and Steel Research Association, 11 Park Lane, London, W.1.

MECHANICAL AND ELECTRICAL ENGINEER by the Directorat General of Municipalities, Iraq—The Crown Agents for the Coloni 4 Millbank, London, S.W.1, quoting M 24694.B.

MECHANICAL ENGINEERS (Tractors) in the Department of Agr culture, Sudan—The Sudan Agent in London, Wellington Hous Buckingham Gate, London, S.W.1, endorsed 'Mechanical Engine (Tractors) 4/4'

PHYSICIST or ENGINEER (university degree in physics or mechanic engineering with mathematics subsidiary essential) to join a researc team investigating deformation of metal, particularly the rollin process—The Personnel Officer, British Iron and Steel Researc Association, 11 Park Lane, London, W.1, endorsed 'Rolling'.

POWER STATION CHEMIST (with a University degree in chemistry or an equivalent qualification) by the Central Electricity Boar Federation of Malaya—The Crown Agents for the Colonies, 4 Mil bank, London, S.W.1, quoting M.28340.B.

RESEARCH FELLOWSHIP established by the Nottinghamshire Counc of the British Empire Cancer Campaign—The Registrar, The Uni versity, Nottingham.

RESEARCH STUDENTSHIP for work on oxides in weld metal—Th Head of the Department of Applied Chemistry, Northampton Poly technic, St. John Street, London, E.C.1.

SENIOR EXPERIMENTAL and ASSISTANT EXPERIMENTAL OFFICER to undertake and assist with experimental work involving a wid range of chemical and physical atomic energy development problems and a SENIOR EXPERIMENTAL OFFICER to design and assemble specia electronic equipment for research groups working on atomic energ development problems, in the Research and Development Branc (Applied Research), of the Division of Atomic Energy (Production) at Windscale Works, Sellafield—The Ministry of Supply, Division o Atomic Energy (Production), Risley, Warrington, Lancs (stating pos applied for).

FUNCTIONS OF THE UNIVERSITIES

In the picture of the development of Owens College into the University of Manchester of to-day which Prof. Charlton has given us under the title "Portrait of a University", stress is laid upon John Owens's insistence that the College should make full provision to meet the particular needs of its surrounding district and the way in which this has influenced developments. Inherent in such thinking is the conception of the university as a regional centre which Prof. B. Dobrée expounded in his Earl Grey Memorial Lecture in 1943; but it is apparent from the discussion on this subject at the Home Universities Conference last December that the universities are not agreed as to the extent or nature of their regional functions or responsibilities. Prof. Charlton's study scarcely helps us either, for although he demonstrates the great value both to the University itself and to the region of that intimate contact between the university and industry, commerce and other activities of the surrounding area which characterized Owens College from the start, he does not deal with important detail and barely mentions the tutorial classes or extra-mural work.

It is appropriate at the present time that the universities of Great Britain generally should consider carefully not merely whether they are fully discharging their regional responsibilities, but even whether in certain directions they may not be doing too much. Like other institutions, they may be called upon to face greater stringencies in the immediate future, in view both of rising costs and the demands of re-armament. The easing of the immediate post-war pressure now that the Further Education and Training Scheme has terminated should provide them with a valuable opportunity for stocktaking and for closer attention to standards. A decline in the student population of the universities is not *a priori* a matter for complaint at the present time. Even an increased expenditure on the universities may well prove to be best distributed over fewer students, and any breathing space which a decreased entry may afford the universities should be utilized in a careful scrutiny of policy and objectives in all branches of expenditure.

In the first place, it is necessary to be clear as to the functions of a university and the broad objectives of its policy. In one particular field a recent broadsheet (No. 328) issued by Political and Economic Planning makes an important contribution. The universities now spend roughly half a million pounds a year on extra-mural work—that is, on the teaching of those who are not full-time students. This is a sum quite considerable enough to justify P E P raising such questions as whether the standard of extra-mural study is sufficiently high to justify acceptance as of university level, and again whether the universities are here undertaking work which could be done as well by others—a question which it is equally pertinent to ask of some of the technical instruction given at the universities, particularly in view of the current debate on higher technological education.

A brief sketch of the growth and extent of the universities' concern in adult education was given by Mr. W. E. Salt, director of the Department of Adult Education in the University of Bristol, in the *Universities Review* last September (see *Nature*, 167, 1; 1951); but the present broadsheet, although entitled "The Universities and Adult Education", examines the work of the extra-mural departments and its place in relation to the rest of the work of the university, particularly in the light of the views expressed in the last report of the University Grants Committee. While recognizing that much of the criticism of the extra-mural work is valid, the University Grants Committee was then prepared to encourage expansion of such work in the belief that "the universities are making, and should continue increasingly to make, a unique and indispensable contribution to adult education". The broadsheet accepts, for the purposes of its discussion, the possibility of achieving work of university standard in university adult classes and that such work is therefore acceptable as a university function. It seeks, however, to define that function more closely and the way this side of the work of the universities is likely to develop in the future in view of the widening purpose and growing importance of adult education in general.

To some extent this survey by P E P duplicates that made by Mr. Salt. It brings out more clearly the point made by Bruce Truscot, both in "Redbrick University" and in "Redbrick and these Vital Days", that under the conditions of to-day the extra-mural work of the universities, and particularly that of Oxford and Cambridge, might be reconsidered in relation to regional responsibilities and the establishment of further universities during the past half-century. When universities are complaining with reason of administrative responsibilities thrust upon them, any opportunity for eliminating unnecessary administrative complications should be seized.

This point could well be examined more carefully, and in this connexion it should be remembered that it is no longer true that adult education can look only to the university for leadership. If, however, the universities wish to lighten their load here, the decision should be taken in the light of some clear and, if possible, agreed ideas as to the principles which should govern their future policy, both in adult education itself and in their regional activities generally. There are directions in which the universities are being urged to extend their activities, and in spite of the value of the bridge between the university and the community which extra-mural activities provide, as the University Grants Committee remarked in its last report, it is important that the universities should not dissipate the resources available by endeavouring to meet all demands made upon them for the provision of adult education.

Such a policy would not only waste university resources but also almost certainly lead to much overlapping with other organizations. Moreover, just as a university cannot consider its regional functions without having regard to the primary, and universal, responsibility implied in its name, so in accepting responsibilities for the cultural life of those without its walls it must be free from sectional inhibitions: it should be prepared to consider requests from any part of the community. Selection and discrimination are essential, but they must not be arbitrary; they must be in accordance with the university's primary purpose.

P E P suggests as the first criterion for discrimination that the main concern of the university should be with studies of a high academic standard or degree of specialization which only the university can effectively supply. This accords with the general opinion at the Home Universities Conference, where, however, Prof. R. D. Waller also pointed out that such specialist and near-vocational work is likely to increase and to involve extra-mural departments in considerable administrative responsibilities which might distract them from other tasks. Like the University Grants Committee, he recognizes the value of the relationship with the local community established in extra-murel work and is prepared to justify such work in general not only by an obligation to meet the utilitarian demands of local interests but also by the university's own sense of social awareness, including the needs of its staff as well as of its community.

In going so far, Prof. Waller makes the university itself, rather than any principle or set of principles, the arbiter; for defining limits for the work of the universities in education, P E P strongly supports the practice of trusting the discretion of extra-mural departments or directors. So far as the length and organization of classes are concerned or the requirement of some minimum educational standards of adult students, it is urged that any other course is undesirable. In practice, however, the scope of extra-mural work has depended largely on the activities of other bodies, and P E P suggests that by laying on the local authorities the new duty of ensuring that "adequate facilities for further education" are available, the Education Act of 1944 may well mean an increase in the demand for those types of instruction which universities are best fitted to provide, as well as a change in relations with local authorities. The work of the universities, together with that of the voluntary associations, will in future be viewed in relation to the whole structure of further education, and university policy should take this into account.

Whatever the scope of the work eventually undertaken by extra-mural departments, the crucial considerations are the preservation of academic standards and the integration of the department with the main body of the university. Both alike turn on the question of university resources, and failure to fulfil either condition has been the prime cause of most of the criticism of extra-mural work and of the waste of resources. In practice, achievement of the first depends mainly on the extra-mural tutor, and the second partly on internal departmental relations and organization.

The difficulty in regard to the maintenance of standards arises chiefly because it is necessary to employ part-time non-university lecturers. On a part-time basis such lecturers cannot have the same opportunities of real contact with the university as those who are full-time members of the university's staff. There is, however, now an established body of full-time extra-mural staff, whose employment raises some of the most difficult problems in university adult education. Even these lecturers do not always possess full staff status, which P E P urges is essential if adult education is accepted as a university function.

By itself it is only a first step, and other measures will often be required to enable such lecturers to make a reality of their university membership and to bring them more into contact with other members of the university staff. Mr. Salt fully recognizes this difficulty in his paper in the *Universities Review*, and to what he said P E P adds little more than the suggestion that it would help in the assimilation of the full-time extra-mural staff with the university, and facilitate the transmission to the outside world of the intellectual attitudes and ideals of a university, if the external staff were enabled to do some internal lecturing also and given the opportunity of joining in the research programmes of internal departments. Such measures would demand considerable organization and adjustment, and for the extra-mural department to become more truly part of the university there must first be readiness to co-operate, a strong interest in its work and a sense of responsibility and unity in the university as a whole. Without them adult education or indeed any aspect of extra-mural work is scarcely worth while undertaking.

Nevertheless, however appropriately and adequately staffed may be the extra-mural department which is the main instrument with which the university fulfils its function in this field, there remains the question of resources. Mr. Salt's suggestion that the extra-mural course itself provides the best test is admirable but scarcely sufficient by itself. The course, he suggests, should make such demands that only the serious student is willing to accept its discipline; but in offering such courses a university cannot fail to take account both of the extent of its other responsibilities and resources and of the general conditions in its immediate region and indeed of the country as a whole.

It has already been indicated that university policy in this field requires to take into account the changes in the structure of further education brought about by the Education Act of 1944. It equally involves consideration of the position and growth of secondary education from this point of view no less than from that of entry to the university. Lord Eustace Percy took up this point in his speech at the Home Universities Conference. What appears to be implied above all in the conception of the university as a regional centre in Prof. Dobrée's lecture or in the views expounded by Bruce Truscot is the interchange of thought between the university and its surrounding region, much as, through working so happily with and through the people of the surrounding community, the University of Manchester has largely been shaped in its development by the needs and outlook of the community and, in turn, in expanding, has served these needs. At the basis of that interchange must lie the production of graduates able to think clearly and precisely and to express themselves lucidly, who possess, as Prof. W. Fisher Cassie remarked, the sound and critical judgment, the personality and the readiness to accept responsibility for which industrial leaders look.

Prof. Cassie suggested that it is in the field of applied science that there has been the most marked failure of the universities to satisfy the requirements of their regions for outstanding men capable of assisting their fellows in the application of scientific truths. It is true that, as he observed, constant contact between the staff of a university and the professional institutions and practitioners of the region is the essential basis of regional co-operation; but there may well be other factors which determine the ability of any one university to provide its region with a sufficient number of outstanding men and women. Entry to a university is not determined primarily by the needs of its region, and there is still a tendency for the most promising students to be attracted to a limited number of universities.

The changes in conception and content of the usual technological curriculum suggested by Prof. Cassie, in spite of their undoubted value, will not necessarily, therefore, suffice; but now that it is desirable to reconsider the ways in which the universities distribute their available resources and indeed the functions the universities should perform, it is more important than ever to insist upon the importance of maintaining, if not of raising, standards. So far as technological or science students are concerned, encouraging them in creative work and the assumption of more responsibility may mean a reduction in numbers and an increase in staff and facilities; nevertheless, the nation's needs, even from the point of view of productivity, will be better served by smaller numbers in whose scientific and technological training critical and expressive faculties have been properly developed. Even when that is conceded, it is still true that the universities should be prepared to co-operate in certain regional activities and developments where these promise to enrich the cultural life of the community, in spite of their cost in resources. The Beveridge Committee on broadcasting, for example, directed attention to the opportunity for experiment in Britain with local stations broadcasting programmes controlled by universities.

Such developments are in line with the sketch of the university of the nineteen sixties with which Prof. Dobrée concluded his lecture, and may indeed afford a new and more effective means by which the universities can participate in adult education. Any such new developments must, however, be considered in relation to the university's first purpose—the pursuit and dissemination of knowledge. Regional developments and adult education are not, and never can be, the universities' first concern, and the extent of the universities' participation in all such extra-mural activities must be determined by the extent to which they are consistent with the maintenance of the highest standards in the universities' primary activities.

THE FIRST AMERICANS

Early Man in the New World
By Kenneth Macgowan. Pp. xviii+260. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1950.) 37*s*. 6*d*. net.

THE evidence for early man in America, before the development of the traits connected with agriculture and a settled life, has hitherto been scattered in a number of technical publications, many of them difficult of access to readers in Great Britain. This book presents the material in a manner both popular and scientific. Mr. Kenneth Macgowan, distinguished in other fields, is an amateur anthropologist; but the book shows that he has read both widely and critically, and the result is clear and generally accurate.

In a book of this length, it is at first surprising to European readers to find forty pages devoted to Old World prehistory; but this is clearly necessary when addressing a public unfamiliar with that field. The author is critical of Mortillet's classification of the Palæolithic, which he regards as a scientific strait-jacket; but it has done good and necessary service even if it has been applied too rigidly, and in the final chapter, which is admittedly speculative, he himself seems to look with too favourable an eye on reports of specifically European types of Palæolithic implement (bearing Mortillet's names) in the New World. He places Harrison, of Eolith fame, in Suffolk instead of Kent, and does not know that Oakley's fluorine analysis work has ruled out an early date for Piltdown man; but these are minor points.

The best source of information on early man in North America is a handbook by H. M. Wormington published by the Denver Museum of Natural History, which appears in the bibliography. This author has, with good reason, abandoned the term Yuma altogether; but it must be noted that Mr. Macgowan has retained it, apparently on purpose. Apart from this, the information given for all parts of America is up to date and, in most cases, as full as the nature of the book demands, though rather more might have been made of Junius Bird's work in south Chile, and his presumed early pressure-flaking sites on the coast of Peru are worth a mention. In connexion with the supposed find of mastodon in association with pottery near Quito in Ecuador, it is certainly a pity that the site did not get more satisfactory investigation (p. 145). Jijon y Caamaño, a distinguished Ecuadorian archæologist, told me that he had the gravest doubts about the association, and dated the pottery as late as the twelfth century. If mastodon had survived until this late date, other evidence of its presence should surely have been found by now either in Ecuador or Peru. The find was described by Uhle, who was concerned in it, and the mention of Maya influence on the pottery is a reminder of the extremely speculative nature of his writings at this time.

Some of the later chapters, containing discussions of diffusion, with special reference to Gladwin's views, and of agriculture, are interesting and stimulating, but relevant rather to a time later than that of the main theme of the book. Chapter 11 contains a statement (p. 208) that no maize had been found with the Coastal Chavin culture, which is not true, since Bird specifically states that it appeared at this very time. Further, we have, since 1949, had more precise information about the date of the appearanc of this culture and of maize than is given here, i the shape of a radiocarbon date of 2665 ± 200 year or about 700 B.C.

The book deserves to be widely read. Not onl does it present a large body of information in readable form, but also it is written in such a way a to encourage its readers to assimilate new facts and t make their theories fit them.

G. H. S. BUSHNELL

ELECTRONIC THEORIES OF ORGANIC CHEMISTRY

Physical Aspects of Organic Chemistry
By Dr. William A. Waters. Fourth edition, completely rewritten. Pp. xii+539. (London: Routledg and Kegan Paul, Ltd., 1950.) 35*s*. net.

WHEN the first edition of this book appeared the application of the wave-mechanical treatment of electron behaviour to organic molecules was in its infancy, the concept of hyperconjugation was unknown, the duality of mechanism of substitution and elimination reactions was generally unsuspected, little was known regarding the kinetics of aromatic substitution, and free-radical chemistry was largely restricted to the reactions of more stable radicals like triphenylmethyl. The very great advances in our knowledge of these topics alone, during the past fifteen years, indicate the magnitude of the task involved in the up-to-date revision of this book which Dr. W. A. Waters has attempted in the fourth edition.

The scope is wider than the title might suggest, since the author attempts the application of "the broad conclusions of the electronic theory of valency" to all the principal reactions of organic compounds. Although the size of the book has been increased by some fifty pages, it is obvious that only the more salient features of such a wide field could be included, and this new edition constitutes a very readable and valuable survey of the present theoretical outlook. The impression is gained, however, that the author has been somewhat hampered and circumscribed by the original framework of earlier editions. There is an unhappy blending of different nomenclatures, and the treatment of some topics is not as up to date as might be expected. The intentional historical development of current ideas from their earlier and cruder precursors is valuable, but curtailment of such treatment would have permitted fuller elucidation and the presentation of a more accurate and complete picture of the conclusions derived from recent extensive kinetic studies.

Thus the whole treatment of ester hydrolysis is based essentially on Lowry's termolecular mechanism which, since it envisages proton-transfer from acidic to basic oxygen as a rate-determining step, would find very limited acceptance to-day. In consequence, Day and Ingold's mechanism of acid-catalysed ester hydrolysis is erroneously described (p. 347) as a bimolecular electrophilic substitution S_E2. Restriction of the account of the effect of substituent groups in 1 : 2-eliminations to those governed by the Hofmann rule (that is, control by the inductive effect) is liable to confuse the reader when he encounters similar eliminations which follow the Sayzeff rule (control by the electromeric effect). A strange and unexpected confusion runs right through the book in the misnaming (p. 436) of the polarizability effect which arises from the reagent-stimulated delocalization of π-electron pairs, as the 'inductomeric' instead of the 'electromeric' effect. Moreover, this nomenclature is erroneously ascribed to Ingold, who, in the reference quoted, clearly assigns the term 'inductomeric effect' to the polarizability effect which corresponds to the *electrostatic* polarization known as the inductive effect. The same erroneous terminology is ascribed (p. 71) to Baker and Nathan's concept of the delocalization of the C—H bond electron-pairs of the methyl group in toluene (now known as hyperconjugation), although these authors, again, recognized its true character and designated it by the same nomenclature—namely, mesomeric and electromeric effects.

In spite of such defects and of a number of misprints, which although not numerous are sometimes rather confusing, the book is a valuable account of the physical background and development of modern electronic theories of organic chemistry and will doubtless be welcomed by all interested in this field.

J. W. Baker

PLANT PATHOLOGY

Plant Pathology

By Prof. John Charles Walker. (McGraw-Hill Publications in the Agricultural Sciences.) Pp. x+699. (London: McGraw-Hill Publishing Co., Ltd., 1950.) 64s.

All students of plant pathology will welcome this work by Prof. J. C. Walker, the distinguished plant pathologist in the University of Wisconsin. It is an introduction to the scientific foundations of the subject, and forms a comprehensive treatment of the better-known plant diseases which may serve as a guide to the general principles of plant pathology.

It is, of course, a matter of personal opinion whether the arrangement of the matter in the book is actually the right one to adopt in such an introductory treatise—whether the sequence should be from the 'particular' to the 'general', or vice versa—but there are obvious drawbacks to the former method, which is the one chosen in this work. Following an introductory chapter on the definition of disease and disease terms and on the classification and economic significance of plant diseases, the reader is taken in the second chapter to a discourse on the history of plant pathology. One doubts, however, whether a student new to the subject can appreciate this information, excellent though it be, at this early stage; and it would perhaps have been more profitable to have extended the number of specific diseases described, especially those of trees, with a few others attributed to the Ascomycetes, which are relatively meagrely treated. At the outset, the young plant pathologist is often far more interested in handling the elements of the subject, the different kinds of fructifications and spores, of sclerotia and rhizomorphs, of morbid anatomy and culture work, than in a contemplation of the historical aspects of the subject. Such a dissertation would perhaps be better reserved for a riper stage of experience.

As a study of this subject must obviously go hand in hand with practical work in the field, greenhouse and laboratory, it is very doubtful whether a start on specific types of disease should have been made with non-parasitic diseases. The multiple symptoms usually presented by these maladies are often very difficult to assign to specific causes, and this section would have been better left until the student had gathered as much information as possible about diseases ascribed to specific organisms capable of being isolated in culture or examined in the plant tissue.

Succeeding chapters are devoted to diseases incited by bacteria (eleven types, with a useful key to the main genera); by Plasmodiophorales (two types); by Phycomycetes (fourteen types, preceded by definitions, but no illustrations, of the diverse kinds of spores and organs in this group); by Fungi Imperfecti (twelve types, prefaced by a scheme of classification in which are included several 'imperfect' forms belonging to the Ascomycetes); by Ascomycetes (thirteen types, with a classificatory outline); and by Basidiomycetes (thirteen types, embracing a number of the smuts, bunts, rusts, *Rhizoctonia*-diseases, and only two diseases of trees). Chapters 10 and 11 deal briefly with phanerogamic parasites (mistletoe and dodder) and nematodes, respectively. These are followed by a comprehensive and excellent account of virus diseases. Other chapters are devoted to the relation of environment to disease development, and host–parasite interactions (this might well have appeared much earlier in the book). Disease control is admirably treated at length in the concluding three chapters under the respective titles, exclusion and eradication, protection, and host resistance.

All the sections and individual types are supplemented by full bibliographies of titles and references. The entire work is beautifully executed (a few typographical errors occur) with 194 figures in line and half-tone, and forms a valuable contribution to the modern aspects of plant pathology.

S. G. Jones

UNCONVENTIONAL HYDRODYNAMICS

Hydrodynamics

A Study in Logic, Fact and Similitude. By Garrett Birkhoff. Pp. xiii+186+3 plates. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1950.) 22s. 6d. net.

This is a book of a very unusual kind, quite unlike any of the standard treatises on hydrodynamics. The author himself says that the material treated "involves a heterogeneous combination of destructive logical criticism, detailed experimental fact, and occasional mathematical sophistication, which may at first seem unpalatable to many readers". The first chapter, entitled "Hydrodynamical Paradoxes", gives many examples of plausible arguments which lead to conclusions opposed to observed facts. It is generally supposed that all these discrepancies between theory and observation are due to a single unjustifiable approximation, namely, the assumption of zero viscosity, but Prof. G. Birkhoff claims that there are others. One of the most disturbing is the possibility that very small causes may sometimes produce large effects. This calls urgently for an investigation into the nature of the corresponding partial differential equations. There are also several cases where apparent symmetry in the causes produces unsymmetrical effects. This chapter is what George Bernard Shaw might have written if he had studied hydrodynamics. After pointing the fallibility of mathematicians, logicians, engineers and physicists, Prof. Birkhoff concludes the chapter with a warning, supported by a photograph forming the frontispiece, against trusting in common sense.

The second chapter, entitled "Recent Progress in Free Boundary Theory", is somewhat similar to the first, but is more constructive and contains some new positive contributions to the subject. It includes an account of two physical parameters which are completely ignored in the classical theory of jets and wakes. The third chapter deals with the use of small models to predict the behaviour of full-scale apparatus, and begins with "a number of simple, yet fundamental mathematical remarks which have hitherto escaped general attention". The author distinguishes between dimensional analysis and inspectional analysis. The former is widely used, but he points out its limitations, which seem to be overcome in the latter. However, for a complete inspectional analysis of hydrodynamical modelling we need fundamentally new theorems about partial differential equations. It is possible that these will be suggested by a study of experimental results. Inspectional analysis is really an application of the mathematical theory of groups, which can also be used to test the validity of hydrodynamical theories even when it is impossible to integrate the corresponding partial differential equations. In the fourth chapter the reader will at last realize that the author's main object is to emphasize the importance of group theory, which is presented as a unifying principle, not only in hydrodynamics but also in other branches of physics and in the theory of differential equations. This is illustrated by a variety of important problems. The fifth and last chapter applies group theory to the concept of 'virtual mass'.

The book will be of great value to those who are able to use it to stimulate their own thoughts.

H. T. H. Piaggio

QUAKERS IN SCIENCE AND INDUSTRY

Quakers In Science and Industry

Being an Account of the Quaker Contributions to Science and Industry during the 17th and 18th Centuries. By Dr. Arthur Raistrick. Pp. 361+17 plates. (London: Bannisdale Press, 1950.) 21s. net.

Much research has gone into the making of this book, and its preparation has evidently been a labour of love for the author. It covers especially the period 1650–1800, during which Great Britain changed over from an economic structure largely agricultural in character to one in which large-scale basic industries, such as coal-mining, iron-founding and engineering, were playing a rapidly expanding part.

About the middle of the seventeenth century, George Fox founded the Society of Friends, soon to be dubbed Quakers. The sect soon attracted unfavourable attention from both the Established Church and the State. Yet, such was the intellectual and spiritual force behind the movement that, in spite of the disabilities imposed on it by law, and the persecution to which members were subjected, its numbers expanded rapidly. Dr. Raistrick points out that before the eighteenth century was well advanced, Quakers occupied influential positions in basic industry, trade, banking and medicine, and appeared on the roll of the Fellows and Council of the Royal Society.

In the first two chapters the author traces in some detail the rise of the Quakers, and the part they played as citizens; and shows by means of statistical evidence that they sprang largely from the class that provided craftsmen, artisans and yeomen. Later, however, they became predominantly middle-class traders.

The next six chapters describe the part played by the Quakers in trade and industry. Among the traders singled out for special mention are the iron masters and the mining companies, including the Quaker Lead Co., which dominated lead mining in Britain during the eighteenth century. The Quakers were prominent in other metal industries, such as brass founding and the smelting of copper and zinc; and reference is also made to the wool staplers and linen drapers. The English porcelain industry, which grew out of the discovery of the china clay deposits in Cornwall, was founded by a Quaker, William Cookworthy.

Dr. Raistrick then discusses the part taken by the Friends in technology, science and medicine. The famous clock- and watch-makers Thomas Tompion and Daniel Quare were Quakers, and so was George Graham, who also constructed a number of astronomical instruments for Greenwich Observatory.

The Friends regarded all natural objects, plant, animal and mineral, as the works of a beneficent creator, to be studied and used for the benefit of mankind, so that it is not surprising to find among their numbers some prominent naturalists and men of science. These included Phillip Miller, superintendent of the Physic Garden in Chelsea, and author of the well-known "Gardener's and Botanist's Directory" published in 1731; William Allen, chemist; William Phillips, mineralogist, and one of the founders of the Geological Society of London, and, most distinguished of all, John Dalton. Among Quaker medical men there occur the names of John Fothergill and John Coakley Lettsom.

During the eighteenth century there was widespread intermarriage among the Quakers, and the family relationships and business ramifications were closely interlocked. The latter pervaded industry throughout England and Wales, and even penetrated into Scotland and Ireland. Many names additional to those quoted here, some important, others less so, receive a mention in this book, and there is a wealth of genealogical and biographical information; but sufficient has been said to indicate its scope.

In the final chapter the underlying causes responsible for the remarkable rise of the Quakers are discussed. Prominent among these were their honesty in business dealings, their lack of avariciousness, and their genuine and practical interest in the welfare of their employees.

Dr. Raistrick's book is fully documented, and is a valuable contribution to the social and industrial history of the years between 1650 and 1800, adding also to our knowledge of the development of technology in that period. It should be read by all to whom such matters are of interest. V. A. Eyles

THE NEW UNIVERSAL DIGITAL COMPUTING MACHINE AT THE UNIVERSITY OF MANCHESTER

University College of Science
PHYSICS Dept.
Upper Circular Rd, Calcutta

By DR. T. KILBURN
Electrical Engineering Laboratories, University of Manchester

IN a previous communication[1], a universal digital computing machine was briefly described. That machine was experimental, and its purpose was mainly to investigate the potentialities of a large-scale machine based on the cathode ray tube[2] and synchronized magnetic drum[3] type of storage. The success of the machine made it possible to begin the design in July 1949 of a new machine, which has just come into service. Whereas this new machine is superficially the same as the experimental machine in that it operates serially, uses the binary system of numbers and has the same digit frequency of 100 kc./s., it has several improved features.

Storage. Experience of the experimental machine showed that the electronic storage capacity of 5,120 digits provided by two cathode ray tubes was rather too small to permit flexibility of programming, and that the subsidiary storage on the magnetic drum of 40,000 digits would be quite inadequate for many problems. In the new machine the electronic storage capacity has been increased to 10,240 digits, and improved operation of the store has been obtained by halving the number of digits stored per tube, and by using the defocus–focus system of storage[2]. The magnetic storage capacity has been increased to 150,000 digits, provision being made for a further increase to a maximum of about 600,000 digits if this is necessary. The magnetic drum is 6 in. in diameter, and along its length of 8 in. there is sufficient space to accommodate 256 separate peripheral tracks. Each track holds 2,560 useful digits; the packing density being 165 digits per inch. The mechanism of reading from and writing on these tracks is described elsewhere[4]. The electronic store can be automatically loaded from, or into, the magnetic store as a result of programmed instructions. These instructions cause a transfer of information in which the contents of any stated track are written on a stated pair of cathode ray tubes or vice versa. Alternatively, if it is more convenient, the transfer of information may be between one half-track and one cathode ray tube. In each case, the correctness of transfer can be checked by a single instruction, and, in the case of an incorrect transfer, the transfer can be repeated, or the machine stopped.

Selection of a particular track for reading is by electronic switching, and for writing, by relay switching.

The time taken for the check, and for any transfer, in which a track is read, is 36 msec. For a transfer in which information is written into a track, this time is increased to 63 msec. to allow time for the relay switching. This discrepancy between the times for reading and writing is not important, because reading is more frequent than writing. This is so because the sub-programmes required during computation are all stored on the magnetic drum.

The accumulator. The facilities for performing addition, subtraction and three logical operations have been retained, together with signed and unsigned multiplication, in which the 80-digit product of two 40-digit numbers is added to the content of the accumulator. Multiplication in which the product is subtracted from the accumulator is a new facility.

The most important engineering change of the accumulator is in the multiplying circuit. In the experimental machine the multiplication time, which depended on the number of 1's in the multiplier, averaged about ten times that for addition. A study of available programmes revealed that if this multiplying circuit was used in the new machine, then about half the computing time of the machine would be spent in multiplication. Consequently, the speed of multiplication has been increased, and, in the new machine, an instruction involving multiplication is selected, interpreted and obeyed in 2·16 msec., as compared with a corresponding time of 1·2 msec. for addition, or any other 40-digit number operation. The increase in speed of multiplication is obtained by using a circuit consisting of a network of adders and delays, arranged in such a way that the sub-products are added together in one operation, instead of sequentially. Although some economy of equipment is achieved by carrying out the multiplication in two parts, controlled respectively by the first and second halves of the multiplier, nevertheless this type of multiplier is expensive and increases the size of the final machine by about 10 per cent (the machine contains 1,600 pentodes and 2,000 diodes). This, however, is judged to be worth while when balanced against the resulting overall increase in speed of operation of the machine.

To simplify the standardization of numbers during the course of computation, an instruction has been provided which produces in the accumulator a statement in binary form of the position of the most significant digit of any selected number in the electronic store.

In the near future, an additional circuit will be installed to generate (in 5·8 msec.) a 20-digit random number as a result of a single instruction. This instruction will be used in calculations concerned with stochastic processes.

The B tube. This facility has been improved to allow still greater flexibility and economy in programming. Eight 20-digit storage locations can now be selected by the three '*b*-digits' of an instruction, and thus any one of eight words may be added to an instruction before it is used.

Further, the *B* tube has been provided with a subtracting circuit, and a sign-testing circuit. Any line of the tube can therefore be used as a 20-digit accumulator for simple arithmetical processes. One important example of this is in counting the number of times that a group of instructions has been obeyed, cycling of control being conditional on the sign of a number in the *B* tube. By this means four instructions are removed from any loop in which counting is required.

The instructions provided enable a number from the electronic store to be written into, or subtracted from, the *B* tube; or a number in the *B* tube to be written into the electronic store. The line of the *B* tube involved in these instructions is stated by the three '*b*-digits'. To avoid the necessity for eight test circuits—one for each line—the instruction 'test the sign of *B*' reads a single circuit, which is recording the sign of the content of that line of the *B* tube which was last used.

The time taken to read, interpret and obey these instructions is 960 microseconds.

Input and output. The input and output is based on teleprinter apparatus using 5-hole paper tape. The input uses a photo-electric tape reader capable of reading 200 five-digit characters per second. The output is by a mechanical tape-punch and/or teleprinter each capable of printing ten characters per second.

The speed of input is approaching the maximum for this machine if an input programme is required to organize the input information. However, the speed of output, which is twenty times as slow, can only be justified if, in general, the time of output is smaller than, or comparable with, the input and computing times together. If this proves to be untrue, an alternative scheme for input and output which has been designed around punched cards may be incorporated at a later date.

Speed of operation. The basic rhythm of the machine is determined by the length of the 20-digit instruction, and not by the length of the 40-digit number. This increases the speed of operation of the machine, as compared with that of the experimental machine, by a factor between 1·8 and 2. If the improvements to the *B* tube, multiplier and other parts of the machine are also included, the overall increase in speed is probably not less than a factor of 3.

It should be noted that this increase has been obtained largely by reorganization, and not by the more difficult and expensive method of increasing the fundamental digit frequency.

Programme of work. It is not proposed to limit the programme of work on the machine to any particular type of problem, but to cover a range of problems chosen for their diversity. Thus, in the immediate future the following items are among those which will be investigated: (1) partial differential equations arising out of biological calculations; (2) simultaneous linear differential equations and matrix algebra, and their application to the cotton and aircraft industries, and electricity distribution; (3) tabulation of Laguerre functions; (4) design of optical systems; (5) Fourier synthesis for X-ray crystallography; (6) design of plate fractionating towers; (7) chess problems.

One aspect of the design of machines is to decrease the number of thermionic valves they contain. Thus, for example, it may be said that in the present machine the multiplication time is too nearly equal to the addition time, and that the size of the machine could be decreased by using a simpler multiplier, say, four times as slow in operation. However, with the present input speed of 1 character every 5 msec., it would then be impracticable to programme the input. One method of overcoming this would be to build circuits to organize the input data; not only would this reduce the flexibility of the programming method of input, but it would also nullify the original intention, which was to reduce the size of the machine. This argument can be extended to include other aspects of design such as the relative merits of serial and parallel machines, various forms of storage and so on. It can be seen that all aspects of machine design are related in a most intricate way, and because of this, the design of present machines has to be based to a great extent on the personal experience and intuitions of the individual designer. Consequently, one further important problem which the machine itself may solve is that when fed with input data describing the reliability of circuits, valves and other components, the speeds of operation of the various possible parts, and all other relative factors, it will give a more correct answer to the problem which still confronts engineers, namely, the design specification of the optimum universal computing machine.

The work described in this article is part of an investigation carried out jointly with Prof. F. C. Williams, in the Electrical Engineering Laboratory of the University of Manchester. I wish to acknowledge the assistance of Mr. G. C. Tootill and the members of the Computing Machine Laboratory and of the members of staff of Messrs. Ferranti, Ltd., who collaborated in the development, and who constructed the machine.

NATURE AND INFECTIVITY OF GRANULAR FORMS OF THE BOVINE TUBERCLE BACILLUS

By Dr. E. M. BRIEGER

Papworth Hospital and Strangeways Laboratory, Cambridge

Dr. J. A. R. MILES*

Department of Pathology, Cambridge

Dr. V. E. COSSLETT and R. W. HORNE

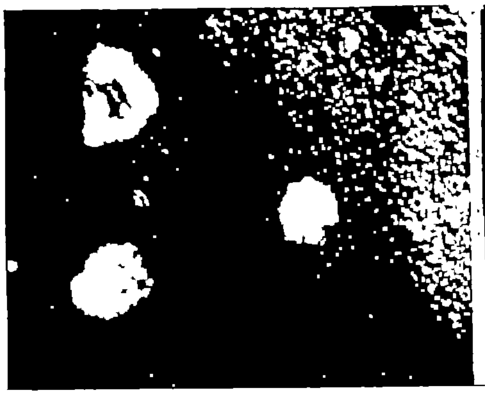
Cavendish Laboratory, Cambridge

THE part played by the 'granular' forms of the tubercle bacillus in the infective process and their place in the life-history of the mycobacterium are still matters of controversy. At present there is a tendency to regard them merely as by-products, seen in old cultures, or as atypical forms produced under unfavourable growth conditions. The question whether the granules are a kind of microspore[1,2] liberated from the mature bacillus, or whether they are merely short rudimentary rods[3,4], has yet to be decided.

The granular forms first described by Much[5] and known as 'Much's granules' have a more definite character. In staining characteristics they are non-acid-fast but Gram-positive. They are said to predominate in tuberculous lesions in which acid-fast bacilli are difficult to find. For a long time Much's granules were regarded as an alternative form of the tubercle bacillus. To-day one is more inclined to regard them as some kind of degenerate form.

---

* Now at the Institute of Medical and Veterinary Science, Adelaide.



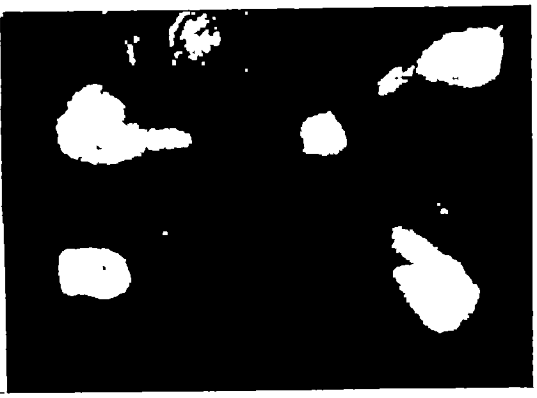


Fig. 1. Granules of 0·5–1·0 μ in size, contained in extracts of high infectivity from rabbits inoculated with *Myc. tub.* (*bovis*). Shadowed with gold-palladium; negative print. Original magnification, 18,000 × ; reproduction, 18,000 ×

Fig. 2. Granules of similar origin and size, but with a projecting rodlet. Preparation and magnification as for Fig. 1

The electron microscope would be expected to reveal the presence and structure of submicroscopic forms, and yet in the few publications on this subject the presence of free extra-cellular granular elements has been seldom mentioned. Intra-cellular granular bodies were described in avian tubercle bacilli by Lembke, Ruska and Christopherson[6], and von Borries[7] interpreted similar structures as Much's granules on rather scant evidence. Brieger and Cosslett[8] found with an avian strain that the dense bodies seen inside the cytoplasm undergo characteristic changes in the first three days of incubation, but there was no definite evidence that free granules occur or that bacilli can develop from free granules. Experiments which are now in progress, employing the technique of differential centrifugation directly on to grids, may throw more light on this intricate problem.

Experiments to demonstrate the presence of granular elements in extracts of infected tissues have been more successful. In recent work by Brieger, Fell and Smith[9], it was shown that tissues removed from rabbits at various intervals after infection with a bovine strain contained only very few acid-fast bacilli, although showing extensive histological changes. If, however, explants of these tissues were cultivated *in vitro* (as tissue cultures), large numbers of bacilli appeared inside healthy-looking macrophages. After about ten days of cultivation *in vitro*, the whole explant became a conglomeration of bacillary colonies. These results showed the need for re-examining the question whether the macrophages, later to become the hosts of large numbers of bacilli, are not, in fact, heavily infected with pre-bacillary elements, which are not demonstrable by present staining techniques.

Fulton and Begg[10] have shown that extracts from tissues infected with rickettsia can be so purified that an opalescent fluid is obtained, after differential centrifugation, which is an almost pure suspension of the organism. Using the same method, Cosslett, Miles and Stoker[11] purified Nigg's virus from infected lungs and spleen of mice. We have now applied the Fulton and Begg technique to the spleens and lungs removed from rabbits seven to twenty-one days after intravenous infection with a virulent bovine strain. Acid-fast bacilli were no longer demonstrable in the fluid obtained after purification and differential centrifugation. In none of the six experiments performed did the electron microscope, phase-contrast microscope or staining methods reveal elements which could be identified as bacillary rods. In itself this would not be sufficient proof that all bacillary elements were eliminated in the process. However, we were also unable to reproduce bacilli by culturing the fluids on a wide variety of media, in spite of long periods of incubation. Microcultures on coverslips did not show any sign of bacillary growth, except in one experiment in which a new and very virulent bovine strain was used. In this case a few acid-fast elements were seen in stained preparations after prolonged incubation.

In spite of the failure to demonstrate acid-fast bacilli, inoculation of a small amount of the fluid (0·2 ml. of a 1 : 5 dilution) into the subcutaneous tissue of the legs of guinea pigs produced a glandular abscess in the draining glands in the course of four to six weeks. Large numbers of acid-fast bacilli were present in the pus, the spleen was heavily infected and a generalized tuberculous infection was present.

The highly infective fluid extracted from the rabbit organs was fixed in osmic acid and samples were placed on metal grids and examined in the electron microscope. Two types of particles were seen: (*a*) particles of about 0·5 μ size or larger; (*b*) small round particles of about 0·2 μ diameter. The larger bodies were obviously related to bacterial elements.

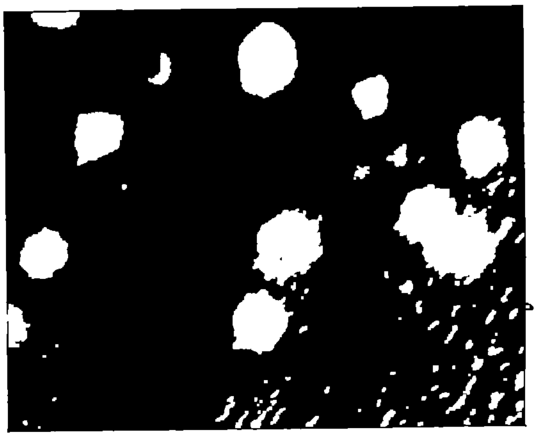

Fig. 3. Granules of 0·1–0·25 μ in size, obtained and prepared as those in Figs. 1 and 2. Original magnification 36,000 × ; reproduction, 41,000 ×

Some had a structure which suggested a set of tightly-packed microrods (Fig. 1). Others had finger-like protrusions and seemed to represent an intermediate stage between granular and bacterial forms (Fig. 2). While the larger particles showed these structures, which distinguished them from contaminants or tissue remnants, the smaller ones (Fig. 3) resembled the smaller animal viruses in size and structure. They were not found in controls prepared from healthy tissues; but it cannot be excluded that they may be normal constituents which are released from cells in pathological conditions.

The fluid was filtered through 0·725 μ A.P.D. 'Gradocol' membranes (which retained *Bac. prodigiosus*) and then did not produce definite tuberculous lesions in guinea pigs. The results of transplanting the glands into normal animals are not yet available[12].

At the present stage, the interpretation of the results must be made with some reserve. Although the presence of normal acid-fast bacilli could only be finally excluded by dilution tests, we may tentatively infer that infection can be caused by particles which are too large to pass the filter but which are not normal rods. These particles may well be identical with Much's granules; our observations show them to have some internal structure. On the other hand, it may be that the smaller particles passed by the filter are essential stages in infection but are unable to produce infection by themselves. In order to build up into the larger, infectious particles, they may require the presence of the living host cell. If this is so, their isolation would break the normal cycle of development in the tissues of the living host.

The fact that the living host cell is necessary for the reproduction and survival of even the larger particles is suggested by the difficulty of culturing them. In one case, when the fluid was injected into a normal rabbit spleen which was afterwards cultured *in vitro*, massive growth occurred, after two weeks incubation, in the juice surrounding the tissue culture. In no case has it been possible so far to grow colonies from the filtrates containing the particles, using the conventional bacteriological media. For this reason, as well as on morphological grounds, the granular particles cannot be regarded as a variant bacterial form, as normally understood. It may well be that they result from the breakdown of the inoculated bacteria in the first stages of infection. They may develop directly into the new generation of bacillary rods which appear at a later stage, or the larger granules may be an intermediate form in such a development, a possibility put forward by Much in his last contribution to the subject[5]. Some of the many problems raised by these observations are now being investigated.

WILLIAM NICOL AND HENRY CLIFTON SORBY: TWO CENTENARIES

By JOAN M. EYLES

AMONG the various sources of information available to the geologist, rock sections, cut so thinly that they can be examined under the microscope by transmitted light, are particularly valuable. The year 1951 marks two centenaries of especial interest in the early history of this technique.

William Nicol, who died in 1851, was not only the inventor of the well-known Nicol prism, which later became an essential tool in examining rock sections by polarized light, but he was also a pioneer in the making of thin sections. Nicol seems to have confined himself to making sections of fossil wood, and did not make rock sections. H. C. Sorby was the first to do this, and it was in 1851 also that his first paper in which such sections were described was published in the *Journal of the Geological Society*. This paper bore the title "On the Microscopical Structure of the Calcareous Grit of the Yorkshire Coast", and, though epoch-making in retrospect, seems to have attracted very little attention at the time.

William Nicol, who was a teacher of physics in Edinburgh during the early part of the nineteenth century, described the construction of his polarizing prism in 1829[1]. Two years later, in 1831, Henry Witham published his "Observations on Fossil Vegetables", in which are given the earliest illustrations of fossil wood seen in thin section under the microscope. In this work Witham gave credit to Nicol for the method of preparing these sections. While the actual technique of cutting the material was no more than that developed by the lapidaries in cutting precious stones and agates, etc., Nicol seems to deserve the credit for realizing it would be of scientific interest if applied to fossil wood. Further than that Nicol apparently did not go, although it seems only a short step from sections of fossil wood to sections of rocks in general. Nicol left his own collection of sections in his will to his friend Alexander Bryson, of Edinburgh, who was himself skilled in making sections, and added to the collection. Nicol's name does not appear in the "Dictionary of National Biography", but there is a memorial tablet in Warriston Cemetery, Edinburgh, which bears the inscription: "In Memory of William Nicol—1768–1851—Inventor of the Polarizing Prism everywhere known by his name".

Turning now to Sorby, he himself, in a lecture entitled "Fifty Years of Scientific Research"[2], said he learnt the art of making thin sections from W. C. Williamson, then a surgeon in Manchester, but later to become first professor of natural history at Owens College and a well-known palæobotanist. Williamson was the grandson of a lapidiary, and as a youth was familiar with the lapidiary's art; and as he was working on fossil teeth and other siliceous material during the eighteen-forties, there seems no reason to doubt Sorby's statement. Sorby said also that the idea of applying the technique to study the structure of rocks came to him in 1849, and he immediately set about preparing such sections; this led to the paper sent to the Geological Society and published in 1851. In spite of this, it has several times been stated by well-known writers, such as Sir Archibald

Geikie, that Sorby got the idea of making rock sections from examining Nicol's collection in Edinburgh in 1856, when it was in the possession of Bryson. The facts, as stated above, were given by J. W. Judd in various obituary notices, but seem to have been disregarded, or even contradicted. The misconception may have arisen because Sorby, in 1857, presented to the Geological Society an important paper on the microscopic structure of rock-forming minerals, and in it referred to Bryson's collection; but if this is the reason, then it shows how little attention Sorby's earlier paper had attracted.

It is therefore worth recalling that Sorby, in his 1851 paper, had employed methods which are now familiar to every petrographer. His sections, mounted in Canada balsam, were "not much thicker than one-thousandth of an inch". He used polarized light, and rotated his specimens between crossed nicols to distinguish between calcite and quartz. In addition to examining thin sections, Sorby separated the constituents of the calcareous grit by chemical and mechanical means. He did not describe in this paper his manner of preparing the sections, but later gave a very clear account in a lecture to the Geological Society of France, in 1860[3]. This latter account was also published in Germany and Spain. Two years after this lecture had been given, Sorby met Ferdinand Zirkel, and described to him his petrographic methods. This encounter was to have far-reaching consequences, for Zirkel took up this type of work with enthusiasm, and in the following year read to the Vienna Academy a memoir describing the microscopical features of thirty-nine different rocks. Subsequent work by Zirkel, Rosenbusch, Fouqué and Michel-Lévy established microscopic petrography as an important branch of geological science, although in the land of its birth it made slower progress than abroad.

In this centenary year of the first account of rock sections, it would therefore be of especial interest if attention were directed to the anniversary by the exhibition in museums of any suitable material. Sorby was so frequently a contributor to the meetings of the British Association that such an exhibit would be particularly appropriate at this year's Edinburgh meeting, where the names of Nicol and Sorby could be fittingly coupled.

OBITUARIES

Mr. H. A. Humphrey

MR. HERBERT ALFRED HUMPHREY, who died at the age of eighty-two in South Africa on March 9 of this year, was one of the most versatile British engineers of recent times. He was best known as inventor in 1908 of the Humphrey pump, which is an internal combustion engine in which the piston is replaced by a water surface. It became an effective means of pumping large volumes of water; the Chingford Station of the Metropolitan Water Board has a set of four large and one smaller Humphrey pumps of 180 million gallons a day total capacity. During the course of his consulting work as a civil, mechanical and chemical engineer, Humphrey had opportunity for exercising his inventive talents in many directions, particularly in the field of gas engines and producers; but not only in a professional capacity, for he would also amuse himself at home in his well-equipped workshop with many devices arising from his fertile imagination.

Humphrey was a distinguished Old Centralian, having been trained as an engineer at the Finsbury Technical College and during 1885–87 at the Central Institution, South Kensington (now the City and Guilds College). There he came under the influence of Unwin, Ayrton, Armstrong and Henrici. He entered in 1887 the works of Messrs. Heenan and Froude as assistant to R. H. Heenan, later becoming manager. In 1890 he was appointed engineer and departmental manager in the Winnington works of Messrs. Brunner Mond and Co., where his ability was soon appreciated by Dr. Ludwig Mond. Until 1901 he remained at Winnington, but thereafter acted with Mond's encouragement as an independent consulting engineer. On account of his work on gas engines and the well-known pump, he soon established a reputation extending to many other countries. He was, however, chiefly concerned with the chemical engineering developments in Brunner Mond's and its associated companies, and later in Imperial Chemical Industries, Ltd., into which these companies were merged. Among other developments he was responsible for erection of coke ovens, benzol extraction plant, caustic soda works, application of gas engines to power generation, and, during the First World War, T.N.T. and ammonium nitrate plants. After that War, he was consultant in the construction of the Billingham plant for synthetic ammonia, for the designs of which he was largely responsible. It was a project on the grand scale, involving a capital expenditure of £25 millions. The boiler and power plant at Billingham, completed in 1929, was well forward of central power station design in Great Britain at that time. He retained a close consulting connexion with Imperial Chemical Industries until late in life. He was also chairman of the South Staffordshire Mond Gas Co., the plant of which he designed.

It was only about two years ago that Humphrey left England to reside at Hermanus, Cape Province, and even there at the age of eighty he was still exercised in several engineering schemes.

The First World War found Great Britain very ill prepared in the supply of explosives, and Lord Moulton, who was chairman of the Explosives Committee, early realized that a great expansion of chemical manufacturing capacity was required. Humphrey was one of the very few engineers available who had the necessary experience in chemical engineering, and through Brunner Mond's he was brought into the organization that Lord Moulton set up. He was responsible for many of the developments which saved Britain from disaster and helped to give an impetus to British chemical industry, which has ever since thrived and expanded. K. B. Quinan was leader of the Explosives Department's constructional programme; he, however, was an American subject, a chemical engineer who came from South Africa. To such men Britain owes a deep debt of gratitude. Humphrey described in the Melchett Lecture to the Institute of Fuel the activities with which he was connected in those days.

Humphrey's influence in training men as chemical engineers within the I.C.I. organization, and insisting on a fundamental approach to the engineering problems encountered, had a great effect on the efficiency of the whole industry. The benefit of his wide experience was generously given to those working with him, and he endeared himself to them.

Humphrey received a number of awards from the engineering institutions, the Willans (1906), the Watt (1913), and the Telford (1897) Gold Medals, the Franklin Medal of the Franklin Institute and the Paris Premium of the Institution of Electrical Engineers (1930). He had three sons and two daughters; one son married a daughter, and one daughter married a son, of Prof. A. V. Hill. He was a member of all three engineering institutions, Civil, Mechanical and Electrical; a Fellow and Melchett Medallist (1939) of the Institute of Fuel, and an honorary fellow of the Imperial College. A. C. Egerton

Dr. D. F. Twiss

By the death on May 23 of Dr. D. F. Twiss, the rubber industry has lost a distinguished pioneer scientific worker and a man universally esteemed by his colleagues in the industry. Born in Birmingham in 1883, Douglas Frank Twiss studied at Mason College and its successor, the University of Birmingham, where he graduated B.Sc. in 1902, afterwards carrying out research in organic chemistry under Prof. P. F. Frankland. During 1904–14 he was lecturer in chemistry at Birmingham Technical School (now Birmingham Central Technical College), and continued research work on organic sulphides and other sulphur compounds and selenides. Dr. Twiss became, indeed, a leading authority on the sulphur group of elements, and was joint author of vol. 7 (oxygen, sulphur, selenium, tellurium) of the well-known "Text Book of Inorganic Chemistry" edited by J. Newton Friend. He was awarded research degrees by the Universities of Birmingham (D.Sc.), and London (B.Sc.).

This early interest in sulphur and its organic compounds was a fitting preparation for Dr. Twiss's real life-work, which lay in the field of rubber chemistry, including vulcanization by sulphur. The opportunity to enter this field came in 1914 when Dr. Twiss was engaged by the Dunlop Rubber Co., Ltd., as its first scientific worker. During his thirty-two years as chief chemist there grew up under his leadership a research team that has made outstanding contributions to rubber science and manufacturing techniques.

Dr. Twiss's earlier work on rubber was concerned with vulcanization by sulphur, the action of organic accelerators of vulcanization, and the important influence of zinc oxide and other metallic oxides on their activity. Of even greater importance to the development of the industry, however, has been the work pioneered by Dr. Twiss on the production of rubber articles directly from the liquid latex, without the usual intermediate stage of coagulating to produce dry rubber which then has to be worked ('masticated') on heavy machinery to render it fit for further processing. From the work of Twiss and his colleagues on latex has developed an entirely new and important branch of the rubber industry, producing vast quantities of cellular (foamed latex) rubber for upholstery, as well as rubber gloves, thread, and hosts of other articles, using methods which in essence are of elegant simplicity, though demanding a rigid physico-chemical control over that complex and sensitive material, rubber latex.

In the midst of these activities Dr. Twiss yet found time to be a willing helper and wise counsellor to many organizations connected with the rubber industry, notably the Institution of the Rubber Industry and the Research Association of British Rubber Manufacturers. There are many who will remember with gratitude and admiration the unfailing help which Dr. Twiss's intensely logical mind was able to give on innumerable problems. Through his work for these organizations, Dr. Twiss did much to foster both technical education and co-operative research in the rubber industry. In recognition of his outstanding services, the Institution of the Rubber Industry in 1934 conferred on Dr. Twiss the Colwyn Gold Medal.

For a man of such attainments and influence, Dr. Twiss was modest and retiring to a degree, but his sincerity of purpose and his conscientious and painstaking discharge of any duty that he undertook—and these duties were many and varied—marked him out as a man above his fellows. His memory will always be an inspiration to those who had the privilege of knowing him. J. R. Scott

Prof. E. L. Watkin

The death of Ernest Lucas Watkin, emeritus professor of mathematics in University College, Southampton, has severed one of the few remaining links with the difficult time when the College was struggling not only to deserve the name of University College, but even to keep in existence.

Prof. Watkin took his degree from St. John's College, Cambridge, being seventh wrangler in the Mathematical Tripos of 1898, still remembered as 'Hudson's Year' for the galaxy of distinguished mathematicians who took the Tripos then. After a short time as lecturer in the University of Bristol, he was appointed in 1904 to the chair of mathematics at Southampton, which he held until 1930. Only those closely associated with him realized the burden of organization involved in a department in which many additional courses were necessary if the College were to survive, including heavy and increasing commitments to the technical side which is still part of the work of the College. He had great administrative ability, and though handicapped by persistent ill-health, carried out unflinchingly work which in these days would be shared by at least two people. His entire disregard of self brought him enthusiastic loyalty from his Department.

After retiring from the chair, he continued to act as deputy registrar and curator of the grounds of the College until increasing age and ill-health forced his permanent retirement.

Prof. Watkin's interests were unusually wide and all were useful to college life. He was an admirable gardener with a good knowledge of systematic botany which he was able to apply as curator of the grounds. He was president of the Chess Club, a strong supporter of all musical activities, an authority on the regulations of most varied and mixed bodies with examination and entrance requirements, and a repository of information on the past history of the College. He combined with all these a gift for friendship, a patient and understanding care for the difficulties of people who often proved tiresome and captious, and a loyalty to his chosen work which is past all praise. A. M. Trout

---

We regret to announce the death of Prof. W. E. Agar, C.B.E., F.R.S., emeritus professor of zoology in the University of Melbourne, on July 14, aged sixty-nine.

NEWS and VIEWS

Expedition to Greenland

A Royal Air Force Coastal Command flying boat, which is visiting Greenland in the course of routine flying training, is taking a small party to carry out a preliminary survey for a more ambitious expedition planned for next year, when geological, glaciological, meteorological and biological work will be carried out. The present expedition, which is privately sponsored and has the approval of the learned societies, including the Royal Society, the Polar Institute and the Royal Geographical Society, will spend a month to six weeks in Greenland. The party is led by Commander (L) C. J. W. Simpson, and will include Capt. M. E. B. Banks, Lieut. F. R. Brooke and Lieut. Angus Erskine. While surveys of the mountainous coastal ranges of Greenland have been nearly completed, little is known of the interior. It is, however, known that in the region called Queen Louise Land in lat. 77° N. there is a range of nunataks 100 miles long, 40 miles wide and rising to about 7,000 ft. To reach this range entails crossing a 20-mile wide glacier. This year's party intends to land on a long lake near the coast and to make its way by a rubber boat to the glacier. With the aid of a Greenland trapper and dog sledges, it expects to cross the glacier and survey a second lake about three miles long that lies along the eastern edge of Queen Louise Land. It is hoped to find on this lake a site for a base camp for further exploration next year, and to discover whether this lake would offer suitable landing for float planes which may be used by the main expedition. It is also intended to bring back geological specimens and to reconnoitre a suitable sledging route through the mountains to the inland ice lying beyond to the westward.

Major Visible Antiquities in Great Britain before 1066

The Archæology Branch of the Ordnance Survey is to be warmly commended for producing a map of the principal visible ancient sites and monuments in Great Britain, of origin before A.D. 1066, which is designed not for the archæologist but rather for the tourist and all those interested in ancient history. The scale is 1/625,000 (or about ten miles to the inch), and this allows the map to be printed on two sheets, one for England south of the line running approximately from Scarborough to Windermere (and including the Isle of Man) and the other for the rest of England and Scotland (including the Scottish islands) (obtainable from the Ordnance Survey, Chessington, Surrey; 6*s.* 9*d.* each sheet). The map is in faded grey with the sites superimposed in black type, these being classified and marked with a distinguishing symbol according to the age group: Palæolithic, Mesolithic, Neolithic, Bronze, Iron, Roman, Dark Ages and uncertain; in addition, Roman roads and canals, and earthworks and frontier defences are shown. It must be stressed that in all cases the emphasis is on the visibility of the site or monument in question; thus, the only sections of Roman roads which are shown are those which are well preserved and recognizable as such and have not been merged into the modern road system. One or two exceptions to the rule of visibility have been made in the case of those sites which, though worked on and filled in, are exceptionally well known for the value to scholarship of the material they have yielded. As is pointed out in the preface to the sheets, the long forms of cairn and barrow have for the most part been allocated to the Neolithic period, and in the same way the round forms to the Bronze, a classification which is to some extent a convention but nevertheless a convenient one. The age group, 'Dark Ages', covers the period from the end of the Roman occupation up to 1066 and is necessarily a 'mixed bag'. Finally, a small number of museums of special interest have been marked, the most important of which is the Pitt Rivers Museum at Farnham. Both sheets contain an index of names for the whole map, and with each name is a brief description (one to a dozen words), age-group, Ordnance Survey sheet reference to the one-inch series of maps, and the National Grid reference point.

Israel National Committee for Theoretical and Applied Mechanics

An Israel National Committee for Theoretical and Applied Mechanics has recently been formed, with Prof. M. Reiner and E. Traum (both of the Hebrew Institute of Technology) as chairman and honorary secretary-treasurer, respectively. An application for admittance as an adhering body has been submitted to the International Union of Theoretical and Applied Mechanics; Prof. S. Goldstein, previously of the University of Manchester and now vice-president of the Hebrew Institute of Technology, Haifa, is a personal member of the general assembly of the International Union. The Committee held a scientific colloquium in Haifa at the Hebrew Institute of Technology during April 23–24. There were two general lectures: Prof. Goldstein gave a review of the present state of the statistical theory of turbulence, and Prof. F. Ollendorf (Hebrew Institute of Technology) dealt with the mechanics of the trajectories of the electrons in electron-lens cathode-ray tubes. The other papers dealt with two main subjects, namely, questions of capillarity and of elastic semi-liquids In the first group M. Ram (Ministry of Agriculture) considered the influence of a capillary film in the soil upon building foundations, while N. Klein (Rheological Laboratory of the Hebrew Institute of Technology) discussed the oil distribution in paper under the influence of gravity. In the second group, papers were given as follows: Dr. A. Katchalsky (Weizmann Institute of Science) presented the modern theory of cross-linked polymer gels; Dr. E. Alexander (Hebrew University) reported upon experiments with a modification of the Gardner mobilometer by means of which the time of thixotropic regeneration can be determined; Prof. Reiner showed how a contravariant measure of strain parallel with the usual covariant measure could account for the centripetal-pump effect in elastic liquids; and Miss I. Braun (Rheological Laboratory of the Hebrew Institute of Technology) demonstrated the effect in rubber toluene solutions.

Radiotherapy and Cancer

The work of the Medical Research Council's radiotherapeutic research unit on the experimental comparison between the effects of gamma-rays and X-rays is recorded in "Researches on the Radiotherapy of Oral Cancer" by Constance A. P. Wood and J. W. Boag (Medical Research Council Special Report Series, No. 267; pp. 148+30 plates; London: H.M. Stationery Office, 1950; 12*s.* 6*d.* net). By means of the disk contour-finder, described fully in this report and illustrated by means of photographs and drawings by P. Howard-Flanders, it is now possible to estimate the dose given and also its distribution in two planes. The histological work on the response of malignant tumours to irradiation, carried out at the Strangeways Research Laboratory, Cambridge, by Dr. F. G. Spear and Dr. A. Glücksmann, is described by these authors in Part 2 of the report and illustrated with photomicrographs. Important conclusions of the report are that the wavelength of the radiation *per se* had no significant effect on the clinical results, that there was no evidence that cancer of the primary site yielded more readily to radiation than did cancer of the glands, and that increase in the proportion of differentiating cells distinguishes epitheliomata responding favourably to radiation from those that failed to respond. The section of the report dealing with the future of research in radiotherapy contains valuable observations on the comparative value of radium beam therapy, high-voltage X-ray therapy and therapy with electron and neutron beams. To this section, Dr. L. H. Gray contributes a valuable article on the use of radioactive isotopes.

Termites and Building in the Tropics

AMONG the recommendations of the Commonwealth Entomological Conference in 1948 was that a simple manual should be prepared, designed for the practical builder and dealing with the protection of buildings and building material from termites. The Building Research Station and the Forest Products Research Laboratory, both of the Department of Scientific and Industrial Research, were asked to undertake the preparation of such a manual, and as a result "The Protection of Buildings and Timber against Termites" has now been published (Forest Products Research Bulletin No. 24; pp. 41+9 plates; H.M. Stationery Office, 1950; 1*s*. 9*d*. net). It is written by W. D. MacGregor, formerly conservator of forests, Nigeria and Sierra Leone, in collaboration with R. C. Fisher, officer in charge of the Entomology Section of the Forest Products Research Laboratory, and should prove of great value to all architects and builders who are concerned in the erection of buildings in countries subject to termite attack. A simple account of the biology and ecological classification of termites is followed by detailed instructions on prevention and control. The greatest emphasis is placed on preventive methods: the use of resistant timbers (indigenous timbers reputed to be resistant to termite attack are listed in an appendix), the impregnation of non-resistant timbers with preservatives, methods of building construction, termite barriers and the like, which will prevent access by termites, and notes on the maintenance of such protective structures. The economic losses sustained from the attacks of termites are enormous; the widespread adoption of the methods set out in this manual should go far towards preventing that serious wastage.

Aids to Science Teaching

ON behalf of Unesco the Ministry of Education has issued another volume in the series "Inventories of Apparatus and Material for Teaching Science". The series has been designed particularly to aid educationists in war-damaged and under-developed countries and takes the form of reference manuals from which the essential equipment necessary to teach science at the various levels may be selected. The lists are based on material not in use in the more highly developed countries. Each manual gives details of the modern curriculum to which the equipment it lists is related. Teachers are therefore given guidance about the kind of course they could undertake and also what equipment would be needed for administrative and experimental purposes. The first volume dealt with the teaching of science in primary, secondary and vocational schools, and the present one with the universities. It covers the subjects of botany, chemistry, geology, physics and zoology and also includes appendixes concerned with common abbreviations and conversion factors used in science, as well as a short list of suppliers of scientific instruments. Copies of the Inventory may be obtained from H.M. Stationery Office, price 12*s*. 3*d*.

British Hat and Allied Felt Makers Research Association: Annual Report

THE third annual report of the director of research of the British Hat and Allied Felt Makers Research Association, covering the year ended August 1950 (pp. 16; Manchester, 1951), records some progress in research, but at the same time directs attention to the fact that comparatively few firms seem to make regular use of the services the Association can offer in dealing with their day-to-day problems or in the provision of technical and scientific information. The fundamental research programme has continued largely on the same lines as in previous years. The particular groups of the keratin molecule which take part in the carrotting of fur have now been determined with some certainty, and evidence has been obtained on the mode of action between fur and mercuric nitrate/nitric acid carrotting solutions. From extensive measurements of the elastic and other properties of wool and fur felt, a scheme of quality assessment has been drawn up which not only gives a quantitative measure of the material properties but also provides a fibre factor which defines the condition of the individual fibres. This fibre factor can indicate differences in original raw materials or degradation or damage in processing. A study of the felting property of wool noils showed that, for any particular type and treatment of wool, there is a maximum degree of felting and that further treatment of the wool only results in a change in shape. On the technological side, methods of addition and the amounts of acid used in processing fur hoods have been reviewed, the damage to animal fibres in dyeing and other processes examined, and a survey of felting machinery begun.

St. Andrews University Chemical Society

THE *Journal* of the St. Andrews University Chemical Society for April 1951 (1, No. 5) contains a number of interesting short papers and provides abundant evidence that the Society is in a flourishing state. D. M. Dunlop describes an Arabic manuscript on alchemy in the University Library, Prof. John Read lectures on historical chemistry as an instrument of culture, Prof. R. D. Haworth on cycloheptane derivatives, and Prof. D. H. Hey on aromatic substitution. Other papers deal with various aspects of chemistry by experts in the fields concerned. The officers of the Society have been fortunate in having available a gift of paper, and they have made good use of it in producing a very attractive record of the lectures given to the Society.

Maritime Meteorology: Conference in Genoa

THE Geophysical Institute of the University of Genoa is organizing a meeting on maritime meteorology, to be held in Genoa during September 20–22, at the same time as the Columbus Celebrations. The meeting will be concerned with the main meteorological problems relating to navigation, with particular reference to the Mediterranean, and the principal themes will be: the vertical distribution of humidity in the air over the sea and over coastlines; the genesis of fogs and visibility at sea; winds at sea and over the coast and their influence on wave motion; and other relationships between the physics of the atmosphere and the physics of the sea. All meteorologists and oceanographers are invited to participate. Further details can be obtained from the Istituto Geofisico e Geodetico dell' Università, via Balbi 5, Genoa.

University of Sheffield: Appointments

The following appointments in the University of Sheffield have been announced: Dr. R. Wheeler Haines, to be senior lecturer in anatomy; G. C. Briggs and W. Johnson, to be lecturers in mechanical engineering; Dr. R. P. N. Jones and M. L. Meyer, to be lecturers in the Postgraduate School of Applied Mechanics.

University of Aberdeen

At a graduation ceremony held in the University of Aberdeen on July 12, the degree of Ph.D. was conferred on the following for the theses mentioned W. C. Bain ("The Propagation of Radio Waves of Very Low Frequency"); Miss M. I. Chalmers ("Protein Digestion and Metabolism in relation to Level of Nutrition"); T. L. Dodsworth ("An Investigation into the Feeding of Beef Cattle with particular reference to the Substitution of Grass Silage for Root Crops"); Miss G. M. Ellinger ("Studies of Factors affecting Bone Development in Rats and Chicks"); K. El Shazly ("Some Studies on Protein Metabolism in the Rumen"); O. C. Farquhar ("The Geology of the Arnage District: A Study of Polymetamorphism"); E. A. Fitzpatrick ("A Study of the Effect of the Nature of the Parent Material on the Development of the Soil Profile with Special Reference to an Area in North-East Scotland"); D. A. Jones ("The Production and Properties of Artificial Crystals"); J. D. Lawson ("Scale Models in Hydraulic Engineering"); F. H. C. Marriott ("The Analysis and Interpretation of Multiple Measurements"); P. A. Orkin ("Studies on Breathing and the Aspiratory Heart of Elasmobranchs"); W. Paul ("The Inter-action of Radiation and Matter"); E. A. D. White ("The Hydrothermal Crystallization of Lithium Aluminosilicates").

Institution of Electrical Engineers: Awards

The Council of the Institution of Electrical Engineers has made the following award of premiums for papers read or accepted for publication during the session 1950–51. Group A: *Kelvin Premium:* B. Adkins; *John Hopkinson Premium:* R. J. Clayton, Dr. D. C. Espley, G. W. S. Griffith and J. M. C. Pinkham. Group B, Non-Section Premiums: *Llewellyn B. Atkinson Premium:* J. H. Mason; *Extra Premium:* H. F. Church; Measurements Section Premiums: *Silvanus Thompson Premium:* Dr. A. H. M. Arnold; *Mather Premium:* J. G. Yates, D. H. Lucas and D. L. Johnston; *Extra Premiums:* E. H. Cooke-Yarborough and E. W. Pulsford; H. H. Rosenbrock and J. R. Tagg; Dr. D. Taylor, J. Sharpe and W. Abson; Humphry M. Smith; J. R. Boundy and S. A. Bergen; O. I. Butler; Radio Section Premiums: *Duddell Premium:* P. A. T. Bevan and H. Page; *Ambrose Fleming Premium:* Dr. J. A. Saxton, G. W. Luscombe and G. H. Bazzard *Extra Premiums:* E. A. Nind and E. McP. Leyton Caradoc Williams; Dr. L. Essen; W. S. Melville R. W. Douglas and Dr. E. G. James; H. B. Rantzen, F. A. Peachey and C. Gunn-Russell; D. G. Kiely, Instr. Lieut. A. E. Collins and G. S. Evans; Dr. A. W. Lines, G. R. Nicoll and Mrs. A. M. Woodward; Supply Section Premiums: *Sebastian de Ferranti Premium:* H. Leyburn and C. H. W. Lackey; *John Snell Premium:* T. F. Monahan; *Extra Premium:* A. C. H. Frost and W. Brittlebank; Utilization Section Premiums: *Crompton Premium:* M. J. J. Cronin; *Swan Premium:* W. D. Chesterman, D. R. Glegg, G. T. Peck and A. J. Meadowcroft; *Extra Premium:* T. H. Petch. Group C: *Heaviside Premium:* Dr. G. G. Macfarlane and Mrs. A. M. Woodward; *Paris Exhibition* (1881) *Premium:* D. B. Hogg; *Oversea Premium for Students and Graduates:* G. W. Donaldson; *Students' Premiums:* C. R. Bates; R. W. Gee; K. F. Tee; J. C. Shaw; P. D. Aylett; B. Berger, D. Bolton; E. J. R. Hardy; I. J. Shelley; D. S. Williams.

Announcements

The Alvarenga Prize for 1951 of the College of Physicians of Philadelphia has been awarded to Dr. George W. Thorn, Hersey professor of the theory and practice of physic, Harvard University Medical School, for his outstanding contributions to our knowledge of the role of the adrenal cortex in health and disease.

Scientific Report Series No. 13, "The Structure and Configuration of Sucrose", published by Sugar Research Foundation, Inc., New York (pp. 40; June 1950; free), contains an interesting historical review of the subject, with full references to literature. The text is by Dr. I. Levi and Prof. C. B. Purves.

British Standards Specifications Nos. 628–32 and 650–56 (1950) on vegetable oils, and 684 (1950) on methods of analysis of oils and fats, give the specifications of several vegetable oils, and standard methods of analysis of these, respectively. The first costs 6*s*. net and the other two 7*s*. 6*d*. net, in each case postage paid, obtainable from the British Standards Institution, Sales Department, 24 Victoria Street, London, S.W.1.

A symposium entitled "Chemical Shortages and the Efficient Use of Processing Solutions" has been arranged by the Scientific and Technical Group of the Royal Photographic Society, in collaboration with the British Kinematograph Society, and will be held on October 3 at Film House, Wardour Street, W.1, starting at 7.15 p.m. Particulars can be obtained from the honorary secretary of the Group (Mr. D. H. O. John, c/o May and Baker, Ltd., Dagenham, Essex).

No. 9 of the Reader's Guides, New Series, published by the County Libraries Section of the Library Association (Chaucer House, Malet Place, London, W.C.1), deals with "Chemical Technology" and can be obtained from the Publications Secretary of the County Libraries Section of the Library Association, County Library, County Hall, Trent Bridge, Nottingham (price 4*d*.), or free of charge through county or municipal libraries. This guide contains a classified list of books dealing with various aspects of chemical technology, including prices, which should be very useful to librarians of research institutions, college and school librarians, and others, as well as to public library officials.

TRANSAMINATION TO PYRUVATE AND SOME OTHER α-KETO-ACIDS

By E. V. ROWSELL
Biochemical Laboratory, University of Cambridge

UNTIL recently, it had become accepted that biological transamination was confined in its scope to the reactions : L-alanine + α-ketoglutarate ⇌ L-glutamate + pyruvate and L-aspartate + α-ketoglutarate ⇌ L-glutamate + oxalacetate.

It is now clear that in numerous organisms and tissues, enzymes exist catalysing the transfer of the α-amino groups of many other L-α-amino-acids to α-ketoglutarate to produce L-glutamate, and from L-glutamate to various α-keto-acids to produce their corresponding amino-acids[1-3]. Hitherto, however, experiments have indicated that either α-ketoglutarate or L-glutamate must be involved as one of the substrates in biological transamination reactions.

Experiments with insoluble particle preparations of rat-liver homogenates show that they are able to catalyse a direct transfer of the α-amino group from various L-α-amino-acids to pyruvate, to give alanine. Rat liver obtained from the animal immediately after death was homogenized in cold $M/10$ phosphate pH 7·8, and the insoluble particles of the homogenate washed several times by spinning down from re-suspension in the buffer, on the high-speed head of the cold centrifuge. The washed particles obtained from a rat liver weighing about 9 gm. were finally taken up to a volume of 15 ml. in phosphate buffer, $M/10$, pH 7·8. Incubations were carried out in test-tubes with the amino-acid under test at a final concentration of 0·03 M, and pyruvate 0·02 M, in a total volume of 2 ml., including 1 ml. of the particle preparation. The incubations took place anaerobically under an atmosphere of nitrogen, at 37° C., and usually for one hour's duration. The reactions were stopped by immersing the test-tubes in boiling water for three minutes, after which the denatured protein was spun down and the supernatants investigated by paper chromatography.

In order to reduce the time involved in the chromatographic investigations, a simple technique has been employed. Sheets of filter paper (7 in. × 4 in.), near the bottom edge of which the samples for amino-acid analysis had been spotted, were held between glass rods, and thus suspended from a glass tripod standing inside a desiccator which contained a thin layer of the chromatographic solvent. Within two or three hours the ascending boundary travelled far enough to separate the two amino-acids concerned, with the appropriate choice of solvents and filter paper. Phenol saturated with water, and propanol–water (4 : 1) have been mostly used. In order to avoid streaking of the spots, which otherwise occurs with phenol in these short runs, a stock of papers was maintained equilibrated in an atmosphere of phenol and water vapour. This technique also effects considerable economy in the consumption of chromatographic solvents, though it is obviously limited to investigations involving only one or two amino-acids.

Amino-acids which will transfer their amino-groups to pyruvate to give alanine, when incubated with these preparations, are L-leucine, L-phenylalanine, L-methionine, L-histidine and L-tyrosine. Control experiments in which pyruvate alone, and each amino-acid alone, were incubated with the washed particle preparations, gave no observable formation of alanine. Other control experiments were carried out with buffer substituted for the tissue preparation, and also with boiled tissue preparations; but in no case was there any non-enzymic formation of alanine. Similar controls have been carried out with negative results in all the experiments described below. Amino-acids which have been shown not to take part in this transamination to pyruvate are L-valine, L-aspartate, glycine and L-tryptophane, though the washed particles will catalyse transaminations between all the amino-acids mentioned, including these, and α-ketoglutarate.

No glutamate was observable on the chromatograms of these experiments and none was detectable in the homogenates, on testing manometrically with glutamic decarboxylase (washed suspensions of *Cl. welchii SR*12). It was nevertheless thought desirable to test the possibility that alanine might be produced by a coupling of two reactions, for example, L-leucine + α-ketoglutarate → L-glutamate + α-keto*iso*caproate, followed by pyruvate + L-glutamate → L-alanine + α-ketoglutarate, the whole process being catalysed by a trace amount of L-glutamate or α-ketoglutarate firmly adsorbed on the particles. If this were the mechanism of alanine production, one would expect that L-aspartate, more readily than any other amino-acid (with the exception of L-glutamate), would form alanine on incubation with pyruvate, since the rate of transamination to α-ketoglutarate is higher from L-aspartate than from any other L-α-amino-acid. However, although chromatograms showed that the particle preparations would catalyse an abundant synthesis of glutamate from L-aspartate and α-ketoglutarate, and of alanine from L-glutamate and pyruvate, no direct reaction of L-aspartate with pyruvate to give alanine was observed. Moreover, no aspartate was observed to have been formed when L-leucine and L-methionine were incubated with oxalacetate, which would be expected if L-glutamate

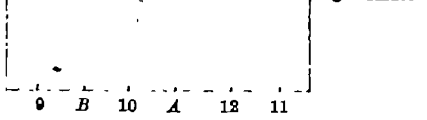

Fig. 1. Short-run chromatogram showing the formation of alanine from phenylalanine (9), leucine (10), and methionine (12), incubated with pyruvate in the presence of washed rat liver particles. None formed from valine and pyruvate (11). Markers containing 0·3 mgm./2 ml. (*A*), and 0·5 mgm./2 ml. (*B*), of both alanine and glutamate, run on the same paper for comparison. Water-saturated phenol on Whatman No. 1 paper

were acting as an intermediate carrier in the formation of alanine from pyruvate. It must be concluded that in the experiments described above there was direct transamination between the amino-acids used and pyruvate.

The supernatants of rat-liver homogenates from the first spinning have been clarified of all visible particles by repeated high-speed spinning and filtration. After prolonged dialysis they have been shown to be effective in catalysing the transamination to pyruvate from those amino-acids which are effective with the washed-particle preparations. These clear supernatant preparations will not catalyse transamination to α-ketoglutarate from L-leucine, L-phenylalanine, L-methionine, or L-valine, and thus constitute an obvious starting point for the purification of the pyruvate transaminase enzyme or enzymes.

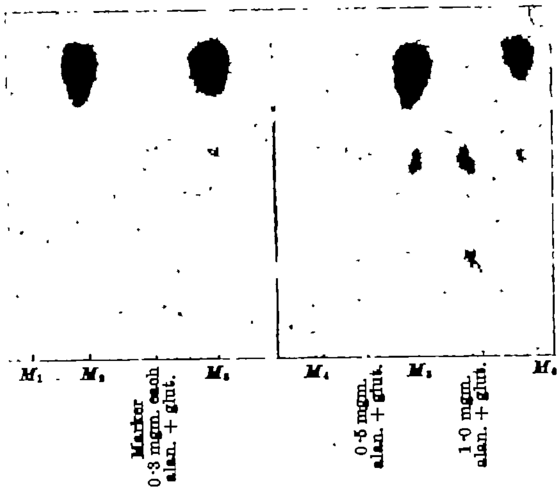

Fig. 2. Short-run chromatograms showing results with washed mouse liver particles. M_1, α-ketoglutarate alone. M_2, L-leucine + α-ketoglutarate. M_4, pyruvate alone. M_5, L-leucine + pyruvate. M_6, L-phenylalanine + pyruvate. Markers containing 0·3 mgm., 0·5 mgm. and 1·0 mgm. of both alanine and glutamate in 2·0 ml. Water-saturated phenol on Whatman No. 1 paper

The hypothesis that L-α-amino-acids are oxidized by the indirect process of transamination to α-ketoglutarate, followed by the oxidation of the L-glutamate thus produced, has been considered. Model experiments using tissue preparations and involving this sequence of reactions have been carried out by Braunstein and his co-workers[4]. The possibility that the oxidation of some L-α-amino-acids in some tissues takes place by the complicated route of transamination to pyruvate, followed by transamination from L-alanine to α-ketoglutarate, and this followed by the co-enzyme I – linked oxidation of L-glutamate, is one that must be considered.

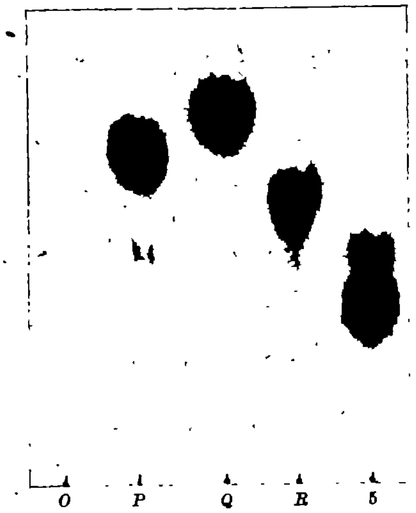

Fig. 3. Short-run chromatogram showing results of incubations with rat liver clarified supernatant. The substrates were α-keto-n-butyrate in each case, with buffer as control (O), L-phenylalanine (P), L-leucine (Q), L-methionine (R), and L-alanine (S). Propanol–water (4 : 1), on Whatman No. 1 paper

In some cases, both with washed-particle preparations and with supernatant preparations, experiments have been conducted in Warburg manometers, containing potassium hydroxide in the centre tube, to find out to what extent L-α-amino-acids are directly oxidized by atmospheric oxygen in these preparations. Washed-particle preparations which gave a synthesis of about 0·5 mgm. of alanine in one hour, under the conditions described above, from pyruvate with L-leucine, L-phenylalanine, and L-methionine, catalysed no oxygen uptake above that of the no-substrate control. Phosphate buffer replaced pyruvate to make up the volume for the manometric experiments. Fig. 1 shows the formation of alanine from L-phenylalanine, L-leucine and L-methionine after their incubation for 45 min. with pyruvate, and may be compared with the following figures for oxygen uptake obtained manometrically over the same period, using the same washed particle preparation :

Water control	11 μlit.
L-leucine	9 ,,
L-phenylalanine	8·5 ,,
L-methionine	8·5 ,,

Clarified supernatant preparations were no more effective in catalysing the direct aerobic oxidation of L-α-amino-acids.

	Pyruvate as amino-acceptor leading to formation of alanine with :				α-Ketoglutarate as amino-acceptor leading to formation of glutamate with .			
	L-leucine	L-phenylalanine	DL-methionine	L-valine	L-leucine	L-phenylalanine	DL-methionine	L-valine
Mouse-liver washed particles (Fig. 2)	+	+			–	–		
Whole dialysed pigeon-liver homogenate	+	+			+	+		
Pig-liver washed particles	–	–	–	–	+	+	+	+
Pig-liver dialysed supernatant	–	–	–	–				
Chicken-liver washed particles	–	–	–	–	+	+	+	+
Rat-kidney washed particles	–	–	–	–	+	+	+	+
Rat-kidney dialysed supernatant	–	–	–	–				

The reversal of the transamination to pyruvate has also been demonstrated. Incubation of washed rat-liver particles with L-alanine and α-keto-*n*-butyrate led to the formation of α-amino-*n*-butyric acid, while with α-keto*iso*caproate they gave leucine, and with phenylpyruvate they gave phenylalanine. (In these experiments the final concentration of L-alanine was 0·03 *M*; that of the keto-acid was 0·025 *M*. The incubation conditions and subsequent operations were the same in these experiments, and in all the experiments to be described, as those detailed above.) These syntheses were not effected when D-alanine or L-aspartate was substituted for L-alanine.

Other animal tissue preparations that have been examined, using the same experimental techniques, for transamination to pyruvate and α-ketoglutarate, are listed in the accompanying table; + denotes their ability, — their inability, to catalyse transamination with the substrates indicated. The whole range of amino-acids tested with each preparation is noted; it may be that other amino-acids would behave differently.

Experiments with dialysed supernatants of rat-liver homogenates show that they are able to catalyse transamination from L-phenylalanine, L-methionine and L-leucine, directly to α-keto-*n*-butyrate to produce α-amino-*n*-butyric acid (Fig. 3), from L-leucine to phenylpyruvate to give phenylalanine, and from L-phenylalanine to α-keto*iso*caproate to give leucine. In these experiments the L-amino-acids were at a final concentration of 0·03 *M* and the α-keto acids 0·025 *M*. (Sodium α-keto*iso*caproate and α-keto-*n*-butyrate were kindly provided by Dr. A. Meister.)

It is evident that biological transamination includes in its scope a much wider range of α-keto-acid acceptors than has hitherto been recognized. It is also obvious, even from the application of this qualitative method for the analysis of amino-acids, that big differences exist between different animal species and tissues in their transaminating ability. Many potential amino-group donors and keto-acid acceptors, including peptides and ketopeptides, will need to be investigated for their interaction in a wide range of organisms and tissues before the full scope of the transamination reaction can be appreciated.

I wish to thank Dr. D. M. Needham and Dr. F. J. R. Hird for their advice and encouragement during the course of this work, and to acknowledge a grant from the Medical Research Council.

ULTRASONICS IN FLUIDS

UNDER the auspices of the Royal Flemish Academy and the United Nations Educational, Scientific and Cultural Organization, an international conference on ultrasonics was held in Brussels during June 7–9 under the presidency of Prof. A. van Itterbeek; the secretary was Prof. A. J. Rutgers. There were about one hundred participants representing most countries of Western Europe, the United States of America and Australia. It may indeed seem that workers in ultrasonics are insatiable in discussing their activities, since this congress followed so closely on the heels of those of Erlangen (1949) and Rome (1950); but the earlier meetings dealt rather with applications of ultrasonics, whereas this year's meeting was concerned entirely with physical measurements and theories.

The subjects proposed for discussion were the following: (*a*) absorption and dispersion in gases and in pure liquids; developments in the field of 'second viscosity of liquids'; (*b*) absorption in electrolytic solutions; relaxation time for ionic interactions; ultrasonic vibration potentials in colloidal solutions; (*c*) absorption in liquid mixtures or in liquids containing solid particles or gas bubbles; (*d*) absorption in liquid helium; 'second sound'.

On the first morning, a lively discussion soon developed on the significance of the 'streaming' of fluid from the surface of an ultrasonic emitter contained in a tube, and the vortices so set up, from the point of view of the dilatational viscosity, which Stokes invoked only to ignore. It was pointed out that similar circulations can be set up in a liquid at quite low frequencies, so that it may be difficult to distinguish any specific effect at high frequencies, when the 'second viscosity' would be expected to show itself. This leads to alternative explanations of the phenomenon, based on the equations of compressible and incompressible flow, respectively. Yet a third theory was adduced in the first category, in which the streaming due to the breakdown of shock wave-fronts was discussed.

A large proportion of the papers presented to the congress were concerned with relaxation phenomena in gases and liquids. On the theoretical side, much argument took place on the best way of representing anomalous absorption, whether by a complex coefficient of viscosity or by single or multiple relaxation times, usually of thermal type.

For water near 4° C., a configurational relaxation between two types of structure having different compressibilities seems best to represent the observed absorption/temperature curve. In applying these theories to actual fluids, with the possible exception of hydrogen, some data have to be taken from the experimental results and it is well, as one speaker reminded us, that we should be clear in our own minds when we are doing this.

On the experimental side, new results were presented for velocity and absorption in organic liquids and mixtures thereof, electrolyte solutions, liquid hydrogen and liquid helium. Besides the common variable-path interferometers and pulse techniques, some data were presented from measurements with the radiation pressure, probe microphone, hot-wire, reverberation and *Schlieren* methods. Interesting reports were also presented of experiments on scattering by solids or liquid bodies surrounded by other liquids, and of the setting-up of potential fields in colloids under the action of ultrasonics.

Measurements of ultrasonic absorption in the critical regions between gas and liquid on one hand and between solid and liquid on the other have recently been made. Glycerine in the neighbourhood of −10° C. exhibits the latter transition, showing a maximum of absorption to 30 Mc./sec. waves at this temperature. Some theories relating to relaxation in this quasi-solid state were advanced, though it is interesting to note that the existence of relaxation frequencies in solids was first discussed by Prandtl for the sonic range in 1928. The ultrasonic relaxations for liquids discovered later bear a close resemblance, in a different part of the gamut, to these.

The final morning was devoted to the propagation of sound in liquid helium II, wherein both acoustic and thermal waves ('first' and 'second' sound) may be propagated. The interactions of these two types and the effect of a temperature boundary-layer which forms at the walls of the containing vessel were discussed from the theoretical point of view by a number of speakers, while experiments were adduced relating to the discontinuity in velocity of 'first' sound at the lambda-point and the theoretical relation which would make this velocity equal to three times the velocity of 'second' sound as absolute zero is approached.

The papers (about thirty-five in all) presented to the conference will eventually be published (in English, French or German) in the *Mededelingen Koninklijke Vlaamsche Academie voor Wetenschappen* (Brussels). It is hoped that summaries of many of the papers will appear in a forthcoming number of the journal *Acustica*.

E. G. RICHARDSON

CATION EXCHANGE AND CLAY MINERAL STRUCTURE

A MEETING of the Clay Minerals Group of the Mineralogical Society, held at Rothamsted Experimental Station, Harpenden, during April 27–28, was largely devoted to a discussion on cation exchange and clay mineral structure, although some general papers were also read and discussed. On the evening of April 27 a lecture on the development of the fuller's earth industry, and the uses of fuller's earth from earliest times, was delivered by R. H. S. Robertson (Glasgow).

The discussion on cation exchange and clay mineral structure was introduced by Dr. D. M. C. MacEwan (Rothamsted), who, with the aid of models, outlined the structures proposed for montmorillonite by Hofmann, Endell and Wilm[1], and by Edelman and Favejee[2], and pointed out that this discussion was, in effect, an attempt to see how far the available data could help towards a decision as to the most probable structure.

Prof. H. Deuel (Zurich) described the preparation and properties of organo-silicon compounds, especially the silanols containing Si—OH groups, and pointed out that Edelman and Favejee have postulated such groups in clay minerals. The previous work of Berger[3], and others, has shown that clays can give organic derivatives, and Prof. Deuel himself has prepared a considerable range of such compounds using 1,2-epoxides, mustard gas, etc. Thionyl chloride gives extremely reactive clay chlorides, which react with, for example, alcohol to give esters, etc. The decrease in cation-exchange capacity after esterification corresponds exactly to the amount of ester groups introduced, and the original cation-exchange capacity returns on hydrolysis. Similar esters prepared from different clay minerals have different properties, an observation which may lead to the development of a method for separation of minerals. In the discussion, H. R. Samson (Rothamsted) suggested that the reactions might be due partly to the hydroxyl groups of decomposition products formed by reaction of the clay with drastic reagents such as thionyl chloride, or of $Al(OH)^{++}$, present in the hydrogen-montmorillonite. Dr. B. S. Neumann (Fuller's Earth Union, Ltd.) inquired whether free silica gel in the samples might not cause such reactions.

Recent attempts to distinguish between the two structures were described by M. J. Méring (Paris), who pointed out that, on the Hofmann–Endell–Wilm theory, structural water should amount to 5·1 per cent, while on the Edelman–Favejee one it should be 6·1 per cent. With normal analytical methods, it is difficult to distinguish between the final removal of sorbed moisture and the beginning of removal of structural water. However, Mlle. Glaeser's use of the Fischer reagent for determination of sorbed water seems promising. Surface areas of calcium- and sodium-montmorillonites with varying water contents and X-ray data for calcium-sodium-montmorillonites, etc., have also been examined. The results tend to favour the Hofmann–Endell–Wilm structure rather than the Edelman–Favejee one. In the discussion, P. Franzen (Amsterdam) suggested that application of the methods of M. Méring to the compounds of Prof. Deuel may lead to considerable further information.

The observation that lithium-montmorillonite loses water irreversibly at a much lower temperature (about 150° C.) than montmorillonite saturated with other cations was discussed by R. Greene-Kelly (Rothamsted). Méring's suggestion that the formation of O—Ca—O bonds[4] between the sheets in calcium-montmorillonite causes the sheets to be locked in position and therefore irreversibly dehydrated can scarcely hold for Li^+, although it might be that Li^+ would react with one of the hydroxyl groups. Attention was directed to other peculiarities of lithium-montmorillonite[5] and lithium-vermiculite[6], in the ensuing discussion, by Dr. R. C. Mackenzie and Miss A. A. Milne (both of Aberdeen). M. Méring stated that he has now abandoned the O—Ca—O hypothesis, while Prof. Deuel suggested that Si—O—Si links might be formed by condensation of two Si—OH groups in separate layers. He also suggested the study of irreversible dehydration in hydrogen-montmorillonite; but several speakers doubted the existence of this material.

Prof. D. McConnell (Ohio) communicated a paper on the calculation of the structural formula of montmorillonite, assuming three cations (silicon, hydrogen and aluminium) present in the tetrahedral layer, that is, partial substitution of $(OH)_4$ for SiO_4[7]. Some doubt was cast on the existence of tetrahedral hydroxyl groups by R. Greene-Kelly, who showed some thermograms for one sample of montmorillonite saturated with various cations, where the relative sizes of the two high-temperature endothermic peaks vary with the exchangeable cation. K. Norrish (Rothamsted) mentioned that Hendricks has suggested that the final endothermic peak may be due to isolated hydroxyl groups unable to condense until the final recrystallization takes place—a suggestion supported by Dr. S. J. Gregg (Exeter), who pointed out the difficulty in removing the last traces of a gas in many decompositions, for example, calcium carbonate, magnesium carbonate, etc. The possibility that hydroxyl groups in McConnell's structure would be partially dissociated and give rise to cation-exchange was suggested by Prof. Deuel.

Experiments on the effect of grinding on micas, described by Miss Milne and Dr. Mackenzie, showed that the cation-exchange capacity of muscovite increases to about 130 m.equiv./100 gm. after nine hours of grinding, remains constant at this value for about another nine hours and then tends to increase again. Corresponding changes observed in the X-ray data indicate almost complete breakdown of the structure by nine hours, with gradual recrystallization into illite thereafter. The cation-exchange capacity of biotite increases with grinding for twenty-four hours, and the lines in the X-ray patterns tend to become diffuse; peculiarities observed with vermiculite cannot yet be explained. In the discussion, R. W. Nurse (Building Research Station) pointed out the severe nature of dry grinding, while Dr. Gregg and Dr. G. W. Brindley (Leeds) both described work on the grinding of kaolinite and halloysite.

In the section devoted to general papers there were three contributions from Rothamsted. The technique employed there by H. L. Nixon and Dr. A. Muir for obtaining electron micrographs of clays was described and a number of excellent electron micrographs shown. In reply to Dr. G. Nagelschmidt (Sheffield), Dr. Muir confirmed that the hexagonal crystals in some of the micrographs are metahalloysite, this having been checked by X-rays. The theory of X-ray diffraction and absorption by oriented flakes and rolled specimens was discussed by K. Norrish and Dr. MacEwan. Equations giving the angular distribution of any particular crystal plane in terms of the distribution of particles have been derived, and the effect of orientation and flake shape on intensities calculated. The calculations give a method of determining the distribution of particles from the variation of intensity of a particular line at different settings of the specimen. Dr. Nagelschmidt and Dr. Brindley both stressed the importance of this theory in quantitative analysis and in structure determinations, and Dr. Brindley explained that, in certain cases, the distribution of particles is obtainable from one photograph. In the third paper, Dr. MacEwan presented a detailed table in which clay mineral types are classified on structural grounds[8]. Use is made chiefly of an extension of the significance of existing names; for example, there are three groups, depending on the number of O, OH layers in the structure, and these are divided into thirty-three sub-divisions through the major divisions: kaolinoids (or kaolin minerals), micas, montmorillonoids, vermiculites and chlorites. This classification was compared with other attempted classifications. In the discussion, Dr. Brindley spoke of the necessity of consideration of such schemes in reaching any definite ruling on nomenclature.

Adsorption isotherms of carbon tetrachloride, water and oxygen, as well as density in carbon tetrachloride, have been used by Dr. Marjorie J. Brown (Exeter) and Dr. Gregg to investigate changes induced in kaolinite on heating. In the region where the water-loss becomes largely irreversible (400–490° C.), the morphology of the grains cannot be greatly changed, since the surface area increases only slightly. A slight decrease in area is observed at about 720° C.; but even at 1,000° C. both area and sorption are still appreciable. H. R. Samson gave some optical evidence supporting the small area change in the 400–500° C. region. Dr. Brown, in reply to Dr. G. Nagelschmidt, indicated that this work is to be extended to montmorillonites saturated with various cations.

Although cold-precipitated hydrated ferric oxide appears to be widespread in soils and clays[9], the conditions necessary for its formation have not yet been determined. The conditions under which it can be formed and is stable in the laboratory were described by Dr. Mackenzie. The changes occurring in the mineral with changes in the mode of preparation have been studied by X-ray, electron diffraction and other methods, and some suggestions were made as to possible modes of origin in Nature. Dr. Neumann reported that similar changes can be obtained with hydrated aluminium oxides, the *endothermic* peak temperature increasing as the precipitation temperature is raised.

The discussion both on the special subject and on the general papers was very valuable and stimulating, but it was obvious that at present no definite agreement as to the correctness of either the Hofmann–Endell–Wilm or the Edelman–Favejee structure can be arrived at. Prof. McConnell's hypothesis has attractive features as a compromise; but at present it is apparently open to some objections, and only if these are overcome can it be accepted.

R. C. MACKENZIE

NEW DEVELOPMENTS IN VISCOMETRY

COLLOQUIUM AT BIRMINGHAM

A COLLOQUIUM on "New Developments in Viscometry" was held by the British Society of Rheology on May 11 in the Department of Chemical Engineering, University of Birmingham. The discussion was introduced with a paper by Dr. R. S. Higginbotham (Shirley Institute, Manchester) and J. J. Benbow (Dunlop, Ltd.) entitled "Some Novel Viscometers for Rapid Measurements under Defined Conditions". Dr. Higginbotham spoke at first on the historical development of rotatory viscometers, including the cone and plate types, mentioning their limitations and discussing procedures for obtaining rheological constants of starch pastes, thick suspensions and soft solids in general over a wide range of shearing stress. A precise knowledge of these constants, including the extent of changes due to thixotropy and dilatancy, is of great importance in selecting and controlling the manufacture of materials in textile printing. Electrical viscometers of the cone and plate types, robust in design and of simple operation, have been designed and found useful for control purposes.

Dr. P. S. Williams (Paints Division, Imperial Chemical Industries, Ltd.) described a new design of co-axial cylinder viscometer with the torsion wire replaced by a strain-gauge assembly holding the inner cylinder. Intended for research purposes with high-concentration suspensions, it has been built to a simple and robust design with a self-centring journal bearing. Results obtained with fine suspensions and gels of silica spheres were discussed with reference to thixotropic changes after different periods of shearing.

Dr. G. F. Eveson and G. H. Higginbotham, of Prof. S. G. Ward's laboratory, Mining Department, Birmingham, discussed results obtained with fine dispersions of spheres in a lead acetate–glycerol medium using different kinds of viscometers, with special reference to the sigma phenomenon which appears to be absent when some types of viscometers are used, due presumably to the kind of flow prevailing. Experiments have been carried out using different gaps between rotating cylinders, allowing for a wide range in the ratio of particle size to length of annular gap. Similar results for slip at the cylinder walls have been obtained under the various conditions. Special research viscometers for dealing with settling suspensions and methods of analysing the results obtained were next described. Following further discussion by the meeting, under the chairmanship of S. F. Freeman (Mars, Ltd.), of proposed new viscometers, visits were made to the laboratories of the University where rheological work was proceeding.

E. W. J. MARDLES

UNIVERSITIES' FEDERATION FOR ANIMAL WELFARE

SILVER JUBILEE

By PROF. A. N. WORDEN

THE British Science Guild, which derived from the British Association for the Advancement of Science, was formed for the purpose of promoting the application of scientific methods and results to public affairs. In 1926 its honorary secretary was C. W. Hume and its most active member Sir Richard Gregory, then editor of *Nature*. The Guild has since been re-absorbed into the British Association; but one of its unofficial offspring, the University of London Animal Welfare Society, or ULAWS (now expanded into the Universities' Federation for Animal Welfare, or UFAW) is still very much alive and has recently celebrated its jubilee by a dinner held in London. It was Major Hume's thesis that the right relations between man and his fellow creatures were a proper study for the attention of university people as such. His first aim in founding the University of London Animal Welfare Society was to secure the support of veterinarians and zoologists; but the veterinary profession was at that time largely at variance with animal welfare movements. A contemporary vivisection controversy found the Society attacked by the anti-vivisection societies and suspected by experimentalists of harbouring in its ranks those of the category since dubbed 'crypto-antivivs'.

Major Hume's refusal to bow before these attacks, or to be discouraged by the initial apathy of the majority of those whose support he solicited, was steadfast. By 1939 hundreds of members and thousands of subscribers had been enrolled, funds from legacies and broadcast appeals had accrued, and the movement had been extended to other universities. In the same year it was decided that the now extensive educational efforts should be backed by original work, and a Scientific Investigations Committee was accordingly formed. Small grants were made for work on rabbit ecology, at the Bureau of Animal Population, Oxford, and for some studies on euthanasia in dogs in the Department of Pharmacology at the same University.

War, the early demise of the Federation's secretary and the destruction of its offices by enemy action naturally hampered many projects. On one enterprise, however, work was continued, and by 1943 it was possible to begin the preparation for publication of a standard text-book upon the care and management of laboratory animals. The support of research workers for such a work was world-wide. Literally hundreds of scientific workers offered their support and the subsequent book, published some four years later, obviously filled a very real need. Only the anti-vivisectionist Press failed to accord it a most favourable reception.

Shortly after the conclusion of hostilities, the Federation made a substantial grant for research on rabbit ecology and control by the Department of Animal Health, University College of Wales, Aberystwyth. It had long been felt that trapping, while a barbarous procedure, was probably an unsound practice from the agricultural point of view, but scientific proof was wanting. These studies continued for more than four years, and attracted the interest and collaboration of official bodies. One of the county agricultural executive committees initiated a widespread attempt at rabbit control based upon methods investigated by the workers in the Department of Animal Health. The reports of the extensive investigations upon control measures, and upon the damage to pastures inflicted by rabbits, are at present being prepared for full publication. The information available by 1950 was placed before the Home Office Committee on Cruelty to Wild Animals. It is evident from its report (Cmd. 8266) that the Committee was duly impressed by the evidence given. The objective presentation to a departmental committee by an animal welfare organization of factual scientific material must have been something of a novelty; but it is, of course, this very combination of humanitarian outlook and scientific approach that characterizes the Universities' Federation for Animal Welfare and places it in the category of a scientific society.

Substantial support has more recently been given to investigations relating to the electrocution and electro-anæsthesia of animals. At present these studies are being undertaken by a veterinary physiologist attached to the Neuropsychiatric Research Centre, Whitchurch Hospital, Cardiff, in the hope of yielding much-needed information on the painlessness or otherwise of electrocution and electro-stunning apparatus now in use, and upon the future possibilities of electroplectic anæsthesia.

Yet another problem supported by the Federation is that of the humane destruction of whales. Here much of practical value has already been achieved in work undertaken at sea by one of the British whaling companies, but the full results are not yet available for study.

These original investigations, while forming a heavy burden upon the slender funds of any charitable organization, have not been pursued to the detriment of educational work at home or abroad. The *UFAW Courier* is widely read, and a great deal of lecturing is carried out by members of the staff and by co-operating men of science. Before the War, membership was extended so as to include not only university men and women but also those members of the learned professions who were not university graduates.

From the first twenty-five years there is therefore much of which the Federation has cause to be proud. Its officials feel, however, that it is still extremely young. They note with satisfaction the birth of kindred ideas elsewhere. The recent formation in the United States of an Animal Care Panel, by veterinarians and scientific workers engaged in animal experimentation, is one such example. From its "temporary war-time address" (284 Regent's Park Road, Finchley, London, N.3) the Federation has built up extensive relationships that bode well for the future treatment of animals. There is no shortage of problems, and even though in some veterinary and laboratory circles there still remains a suspicion of anything termed 'animal welfare', this prejudice will finally be broken down by further deeds. In respect of the laboratory world alone, it is fair comment that the Federation's activities have tended to aid both the well-being of the animals themselves (which is largely a husbandry problem) and the value of them for experimental purposes. The Federation is concerned not with the sterile argument of whether experiments on living animals are justified, but with the best conditions in which laboratory animals may be maintained. Dr. E. C. Morland, formerly editor of the *Lancet*, wrote to Major Hume after the publication of the "Handbook" to congratulate the Federation for ". . . mediating with rare insight between two irreconcilable combatants. It relieved my mind of the misery of watching it go on, year in and year out and, it seemed, for ever. Accept the thanks of one who knows."

CARNEGIE TRUST FOR THE UNIVERSITIES OF SCOTLAND

ANNUAL REPORT FOR 1949–50

THE outstanding feature of the forty-ninth annual report of the Carnegie Trust for the Universities of Scotland*, which covers the academic year 1949–50, is the increased expenditure on research schemes, the total of £34,088 being the largest thus far required in the history of the Trust for postgraduate study and research. From surpluses at its disposal from the eighth quinquennial distribution to the universities and colleges, the Committee made extra grants of £13,000 each to St. Andrews and Aberdeen, and £20,000 each to Glasgow and Edinburgh. From the beginning of the year under review, the value of the research scholarships was raised from £250 to £300, the senior scholarships from £400 to £450, and the fellowships from £700 to £800 with a possible further £50 for exceptional expenses. Expenditure on these awards now exceeds £12,000 a year, and the Committee proposes in future to invite nominators to these scholarships to say privately whether a trial year in the first place is desirable. During this trial the scholarship would be £200 and would be tenable at the parent university under close supervision of the nominator or other member of the university department in which the scholar proposes to work.

Block grants to the four Universities for research at home or abroad by members of staff have been extended, from October 1950, by a tentative scheme to involve not more than fifteen specially selected members of the university staffs in each year who will be given leave of absence for three to twelve months to prosecute lines of research on which they have already made such progress that conference with workers in the same fields in other countries is highly desirable. Six of these awards each year will be for travel to, and maintenance in, the United States. The Committee is also continuing, particularly in co-operation with the publications committees of the universities, its system of guaranteeing against loss books which are the fruit of sustained research on the part of their authors, but which are of a nature likely to have only a limited public. Further assistance has also been given to learned societies in Scotland in the publication of their transactions and journals, as well as, through the universities, to the Third Statistical Account.

Awards of fellowships, scholarships and grants for 1950–51 are detailed in the report, which also includes, besides reports on the work of investigators under the research scheme during the year 1949–50 and from the superintendent of the laboratory of the Royal College of Physicians, lists of publications by fellows, scholars and recipients of grants and of assisted papers, together with details of assistance to students and an abstract of accounts for 1949–50. Assistance to students has been confined to those who, for adequate reasons, had no bursary from a local education authority or whose circumstances and exceptional merit enabled the Committee to give assistance under Clause B of the Trust Deed. The average payment per beneficiary was £21, as against £15 in previous years, and three hundred students benefited. The Committee notes with regret a severe decline in repayments by former beneficiaries, only £1,160 having been repaid as against £5,379 in the peak year of 1946–47.

CHEMISTRY AT THE UNIVERSITY OF SYDNEY

GIFT FOR NEW BUILDING

AN anonymous donor has recently presented to the University of Sydney a sum of £100,000. This, according to the official announcement by the vice-chancellor, Prof. S. H. Roberts, has been "given and accepted on the sole condition that it is to be used for the building of the first wing of a new Chemistry School, and in the hope that it will stimulate other donors".

Chemistry in the University of Sydney has a history going back a century, beginning with the arrival in 1852 of the Hon. John Smith—previously assistant professor of chemistry in Marischal College, Aberdeen—as "Professor of Chemistry and Experimental Physic". About 1874 a separate chair of chemistry was instituted, with Archibald Liversidge as its first occupant. Following him have been C. E. Fawsitt (1907–46) and R. J. W. Le Fèvre (1946–). From 1913 there has also been a chair of pure and applied organic chemistry, all four holders of which—Sir Robert Robinson, John Read, James Kenner, J. C. Earl—are now living in Great Britain.

Of the laboratories set up by Smith no signs remain. Those now in use are grouped around a nucleus laid out in 1889 by Liversidge. At intervals, various temporary and permanent additions have been made, so that in 1951 chemistry has available some 100,000 sq. ft. of floor space. This is not at all conveniently or efficiently arranged. In the University of Sydney a large number of students take chemistry in the earlier years of their degree courses, and a particularly heavy commitment is what, in Great Britain, would correspond to Intermediate B.Sc. classes. For example, during the 1947 session laboratory facilities for some 2,100 such students had to be provided. Although by now (1951) this number has become approximately 1,100, it is not expected to become smaller in the foreseeable future.

---

* Carnegie Trust for the Universities of Scotland. Forty-ninth Annual Report (for the Year 1949–50), submitted by the Executive Committee to Trustees on February 26, 1951. Pp. iv+70. (Edinburgh: Carnegie Trust for the Universities of Scotland, 1951.)

Indeed, from 1953 onwards, it is anticipated that enrolments at Australian universities will rise by perhaps 1,000 per annum until about 1958, and thereafter by about 2,000 per annum until they reach a peak in 1965. These forecasts are based partly on the jump of the Australian birth-rate occurring in the late 1930's following the depression, and upon the growing flow of migrants to the Dominion. Furthermore, it is hoped that many South-East Asian students will in the future go to Australia for higher education or postgraduate work. It is intended, therefore, to utilize the present benefaction to proceed as soon as possible with the erection of a sufficient part of the eventual building to accommodate the large group of elementary students just mentioned, and thus enable them to leave the present factory-like, fibro-cement, temporary laboratory they now occupy.

Completion of a new Chemistry School must be necessarily dependent upon the provision of funds. It will be a development of benefit indirectly to a number of other departments of the University. These, at present working under extreme difficulties because of shortage of space and lack of modern facilities, will be able then to expand into much of the accommodation previously used by chemistry.

VOLUME TABLES FOR ESTIMATING TIMBER IN GREAT BRITAIN

FOR a century and a half at least on the Continent of Europe, for example, in Germany and France, volume tables have been in existence which enabled the forester and the timber merchant to calculate the volume of timber in crops of standing trees of various age classes, without having actually to measure the crops. These tables were based on a large number of measurements of selected areas of the same age, situation and soil, and so forth, carried out over a number of years and in blocks of forest which had passed through more than one rotation of careful management.

In tropical forest regions the first attempt to prepare volume tables was begun in India. The difficulty here was that the forests were virgin ones and not regular crops grown by man for at least one rotation, and allowances had to be calculated and allowed for. The user of the table therefore had to make certain allowances to the figures of volumes contained in the table. The Forestry Commission has been undertaking work of this description in Great Britain, and last year it published general volume tables for oak, beech, Scots pine and European larch*; other tables are promised for birch, Corsican pine, Japanese larch, Norway spruce, Sitka spruce and Douglas fir.

The volume tables for broad-leaved species, including the one for beech, give average hoppus (or 'cubic foot quarter-girth') volumes over bark for trees of a given breast-height quarter-girth (abbreviated as B.H.Q.G.) and timber height. Breast height is taken at 4 ft. 3 in. above ground level (on the upper side of the tree on slopes) and volumes are measured, in lengths coinciding with 'stops', from ground-level to timber height, that is, an over-bark top diameter of 5–6 in. or to the point where the stem loses itself in the crown, whichever comes first. A 'stop' is a point on the stem at which there is a sudden change in diameter or a pronounced bend. No allowance is made for the stump, and branch wood of all dimensions is ignored.

The volume tables are intended to assist foresters, landowners and others in estimating the cubic contents of standing timber; but, in order to achieve this purpose, their uses and limitations must be clearly understood. Trees with identical breast-height girths and heights may differ from one another in the rate of taper. The tables cannot therefore be relied upon to give accurate estimates of individual tree volumes; they can only be expected to give satisfactory estimates for the aggregate volumes of a group of trees or of a whole stand. Even whole stands may differ from one another in stem form, although usually in a lesser degree, and it is therefore always advisable when first using a general volume table under a given set of conditions to test it on a number of felled stems grown under those conditions. If the table shows a definite bias, volume table estimates of standing timbers on that site will have to be adjusted accordingly.

Unless a stand is very small, it is usually not necessary to apply the volume table to every single tree. In old hardwood stands it is probably best to measure the breast-height quarter-girth and to estimate the timber height of every *n*th tree, the value of *n* being chosen so that there will be at least one hundred such trees; for example, if there are five hundred, every fifth tree would be measured. The volume of the stand is then obtained by multiplying the total volume of the measured trees by *n*. In young hardwood stands and conifer stands of all ages, in which stem-length varies less erratically, it is usually best to girth all trees in order to determine the mean girth—that is, the girth corresponding to the mean basal area of the stand—and then to measure the heights of a number of trees near that mean girth in order to get a mean height. The volume for this mean girth and height, as derived from the volume table, multiplied by the number of stems, gives an estimate of the standing volume of the crop.

When estimating the volume of standing timber in large stands or whole forests, these or similar methods will usually be applied, not to the whole area but only to a representative sample of it. It requires a knowledge of sampling theory and of local conditions to find the most efficient sampling technique in any particular case; but for many practical purposes and for working plan enumerations in particular, a ten per cent sample consisting either of parallel strips $\frac{1}{2}$–1 chain wide or of small circular plots, spaced at regular intervals over the whole area, will often give efficient and unbiased estimates of adequate precision.

Oxygen Affinities of Respiratory Blood Pigments in *Serpula*

Serpula, a marine annelid worm, is the only animal known to possess two respiratory pigments in its blood, namely, chlorocruorin and hæmoglobin[1].

The hæmoglobins of mammals and of a variety of invertebrates have a considerably higher affinity for oxygen than the chlorocruorins of Serpulimorpha[1,2], a high affinity meaning that the pigment is oxygenated at a low pressure of oxygen. If, therefore, a mixture is made of an oxychlorocruorin and human oxyhæmoglobin, and then oxygen is progressively removed from the solution, a spectroscope shows that the α-band of oxychlorocruorin vanishes before the α-band of oxyhæmoglobin. But when the naturally mixed pigments in the blood of *Serpula* are gradually deoxygenated, the two α-bands disappear simultaneously. This means either that the hæmoglobin of *Serpula* has an unusually low affinity for oxygen, like that of the chlorocruorins hitherto examined, or that the chlorocruorin of *Serpula* has an abnormally high oxygen affinity.

This interesting point has remained unsettled since the time that the duplicity of the *Serpula* blood pigment was discovered, owing to the difficulty of finding big specimens of *Serpula*, which in most places is not an abundant serpulid. I have, however, now been fortunate in getting several moderately large live individuals of *S. vermicularis* L. from Plymouth. The worms were cut up in water and the liquid centrifuged, giving a solution with the brown colour characteristic of the blood of this genus. It is known that the relative quantities of the two blood pigments in *Serpula* vary with the age of the animal; in the solution which was prepared this time the two α-bands were equal in intensity. To a small optical glass tube containing about 0·5 ml. of the diluted *Serpula* blood, enough human blood was added to double (approximately) the intensity of the α-band of oxyhæmoglobin. Then a very small crystal of sodium dithionite was dropped in to remove most of the dissolved oxygen from the solution. The result was that, viewed with the microspectroscope, the α-band of oxychlorocruorin was seen to vanish, while the intensity of the α-band of oxyhæmoglobin was about halved. It is clear that only the human respiratory pigment remained in the oxygenated state; the hæmoglobin of *Serpula* was deoxygenated, together with the chlorocruorin. On aeration the bands reverted to their initial strengths. The experiment, which was repeated four times, showed that the chlorocruorin of *Serpula*, like other chlorocruorins, has a low oxygen affinity, and that likewise the hæmoglobin of *Serpula* has a low oxygen affinity. In this property the latter pigment differs from the hæmoglobins of other invertebrates[2] but resembles those of some fishes[3].

The hæmoglobin of *Serpula*, like all other hæmoglobins, contains protohæm. The chlorocruorins have their own peculiar hæm, chlorocruorohæm[4], and their proteins differ from globin of hæmoglobin[5]. It may well be that in the hæmoglobin of *Serpula*, protohæm is united to the protein of chlorocruorin and that this endows it with its low oxygen affinity.

Density of Bottom Animals on the Ocean Floor

Our knowledge of the density (number and weight per sq. m.) of bottom animals in deeper waters is very scanty, since very few quantitative samples have hitherto been taken, and none at depths exceeding 1,000–1,400 m. It may therefore be of interest that the Danish Deep Sea Expedition in the *Galathea* has succeeded in taking thirteen quantitative samples with a 0·2 Petersen grab off the West African coast at depths between 820 m. and 3,782 m. The weight and number of species and specimens per sample are given in the accompanying table.

Locality	Depth (m.)	Weight of living animal per sample (gm.)	No of species	No. of specimens
Off Takoradi	1,480	0·3	3	9
Off the Congo	2,680	0·1	1	1
,, ,,	1,480	0·3	8	3
,, ,,	820	0·9	4	6
,, ,,	985	0·2	2	2
,, ,,	1,150	0·2	1	1
,, ,,	1,460	0·4	4	4
Off Angola (Lobito)	3,782	0·62	4	6
,, ,,	2,430	0·42	2	2
,, ,,	1,508	0·3	4	7
,, ,,	1,200	0·6	6	17
,, ,,	1,006	0·8	4	4
,, ,,	985	0·5	4	8

Summarizing these results, it will be seen that the average weight of living animals in the six samples off the Congo from between 820 m. and 2,680 m. is 0·37 gm. per sample, that is, 1·85 gm. per sq. m. The number of species is on an average 2·5 per sample, that is, 12·5 per sq. m., and the number of specimens 3 per sample, that is, 15 per sq. m. These figures seem surprisingly high compared with those hitherto found at depths of about 1,000 m. in the Mediterranean, off Scotland and off Greenland. If the figures for the Angola coast are considered, the average weight per sample represents 0·5 gm., that is, 2·5 gm. per sq. m., with 3 species and 7 specimens per sample, that is, 15 and 35 respectively per sq. m., which seems to be a very high figure considering the fact that the depths are between 1,000 m. and 4,000 m.

There seems to be a difference between the deep sea off the Congo and off Angola, since the density of specimens appears to be distinctly higher off Angola. This is in good agreement with the fact that the productivity of the sea increases towards the south due to the influence of the Benguela Current and the upwelling water.

If we consider the results of the investigations with the Petersen grab in more shallow waters and compare the tropical part of West Africa (off the Volta and off the Congo) with subtropical African waters (off Angola and off Walvis Bay) there is a very striking difference. Off the Volta and off the Congo the number of living animals per sq. m., even at small depths, 20–200 m., is very low, about 30–40 gm. per sq. m. at depths of about 10–20 m., falling to 1–10 gm. at greater depths. Off Lobito and the Cunene River the figures are somewhat higher, about 40–100 gm. at more shallow depths, 5–10 gm. at greater depths. Off Walvis Bay the figures are quite different, namely, 150–300 gm. living animals per sq. m. down to about 100 m., and thus resembling the order of magnitude in North European waters, while the density off the tropical parts of the African coast is much lower than that in the North Sea, in Iceland waters, etc.

Our experience from the first part of the Expedition is that there are no technical difficulties in taking quantitative samples with the 0·2 Petersen grab at depths of 4,000 m. and more, and it is now planned to carry through such sampling in the different deeps of the oceans as well as off the different coasts of the continents for the purpose of comparing the density of the fauna in the different parts of the oceans.

Inhibition of the Biosynthesis of Tobacco Mosaic Virus by Thiouracil

SUBSTANCES capable of inhibiting specifically the formation of viruses are of obvious practical and theoretical interest. In the case of plant viruses, the composition of which are relatively simple and known, the opportunity exists of correlating the structure of an inhibitor with that of virus constituents and thereby gaining some insight into the problem of the biosynthesis of virus.

With this in view, we have investigated the effect of a series of substances on the rate of formation of tobacco mosaic virus in isolated tobacco leaf tissue. Of these, one, thiouracil, has proved to be a potent inhibitor at extremely low concentrations. The inhibitory effect is partially reversed by uracil, one of the pyrimidines which can be isolated from tobacco mosaic virus nucleic acid. The experimental procedure and results are briefly described here.

A healthy tobacco (*N. tabacum*, var. White Burley) leaf, 13 in. long, was detached from the plant and inoculated by rubbing with a solution containing 200 μgm. of purified tobacco mosaic virus per ml. The leaf was placed under a bell jar and maintained at 24° C. in 120 ft.-candles of fluorescent lamp illumination for 24 hr. Disks of blade tissue 12 mm. in diameter were then removed from the leaf, washed in sterile distilled water and floated on one-half strength Vickery's solution containing various concentrations of thiouracil in Petri dishes. These were maintained under sterile conditions at the above temperature and light intensity. Periodically, four disks were removed and analysed for tobacco mosaic virus by the method already described[1]. As we have previously shown, leaf tissue maintained in the absence of thiouracil under these conditions is capable of synthesizing amounts of tobacco mosaic virus comparable with those found in intact inoculated plants.

The effect of thiouracil on the amount of tobacco mosaic virus formed 220 hr. after inoculation is shown in Table 1. Complete inhibition of synthesis of tobacco mosaic virus is attained at a concentration of $4 \cdot 3 \times 10^{-5}$ *M* thiouracil. In all concentrations of thiouracil, the tissues remained turgid and epidermal cells exhibited protoplasmic streaming for as long as 300 hr. after inoculation. Hence, the effect of thiouracil on the formation of tobacco mosaic virus cannot be ascribed to death of the tissue. A series of experiments comparable to that described in Table 1 has been carried out with the same result.

Table 1. EFFECT OF URACIL AND THIOURACIL ON THE BIOSYNTHESIS OF TOBACCO MOSAIC VIRUS IN TOBACCO LEAF TISSUE

Leaf	Uracil ($M \times 10^{-5}$)	Thiouracil ($M \times 10^{-5}$)	Time of analysis hours after inoculation	Virus present (μgm./100 mgm. tissue wet weight)
A	0	0	220	289
A	0	0·9	220	227
A	0	1 7	220	75
A	0	4 3	220	10
A	0	6 9	220	13
A	0	8 6	220	13
B	0	0	212	202
B	0 9	4·1	212	20
B	4·7	4 1	212	59
B	9 3	4·1	212	180

That the inhibitory effect of thiouracil is partially reversed in the presence of uracil is also shown by Table 1. These are results of an experiment similar in detail to that described above, except that disks were floated in nutrient containing the concentrations of uracil and thiouracil stated.

In a separate experiment similar to those cited above, the infectivity of homogenates (10 ml. of phosphate buffer, *p*H 7·0, per 100 mgm. of tissue) of inoculated leaf tissue cultured in nutrient medium containing various concentrations of thiouracil was determined by the half-leaf method using *N. glutinosa*. As shown in Table 2, the inhibition of virus formation caused by thiouracil is apparent from the reduced infectivity of tissue cultured in the presence of this substance.

Table 2. INFECTIVITY OF HOMOGENATES OF VIRUS-INOCULATED TISSUE CULTURED FOR 312 hr IN VARIOUS CONCENTRATIONS OF THIOURACIL

Thiouracil conc. ($M \times 10^{-5}$)	Local lesions formed: Average No./half-leaf	Per cent of control half-leaf
0	12	19
2 0	12	22
4 0	6	14
7 0	4	9
10 0	1	3

Note *N glutinosa* half-leaves were rubbed with phosphate-buffer (*p*H 7 0) homogenates containing 10 mgm. of tissue per ml Control halves were rubbed with solution containing 40 mgm. of virus per ml Lesion counts are averages for 8 half-leaves

These results suggest the possibility that thiouracil blocks synthesis of tobacco mosaic virus by interfering with some aspect of uracil metabolism which is normally essential for formation of the virus. This effect may be due to interference with the incorporation of uracil into the virus particle, or to an inhibition of a process more remotely related to the biosynthesis of the virus. The possibility also exists that virus-inoculated leaves may accumulate some precursor of tobacco mosaic virus under the influence of inhibitory concentrations of thiouracil. These aspects of the problem are now under investigation.

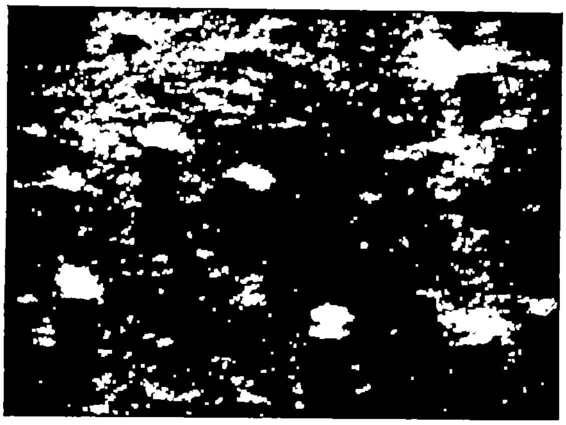
Structure of Sannhemp (*Crotalaria juncea* Linn.) Mosaic Virus with the Electron Microscope

A MOSAIC virus of sannhemp (*Crotalaria juncea* Linn.) was crystallized[1] at the Indian Agricultural Research Institute following the method suggested by Bawden[2]. Later, the virus was crystallized, employing the method of Markham and Smith[3] used for isolation and crystallization of turnip yellow mosaic virus. Control experiments conducted with the expressed sap of the leaves of healthy sannhemp plants and subjected to treatment similar to that given to the infective sap showed that no such crystalline substance could be obtained from healthy material. Solutions of the crystalline preparation indicated positive results in every inoculation test, and typical symptoms were produced on sannhemp plants. Raychaudhuri and Ramamoorty[4] studied the light-absorption curve of 0·11 per cent crystalline solution of sannhemp mosaic virus in a centimetre layer of the solution on a Hilger Spekker spectrophotometer *E*2, and observed two maxima, at 2770 A. and 2632 A., and a third one at 2958 A., with an inflexion point at about 2146 A. A preliminary study has now been made of the size and shape of the structures considered to be virus particles, as observed in the electron-micrographs of the crystalline preparation. The micrographs have been made with the electron microscope installed in the Institute of Nuclear Physics at Calcutta[5].

A micrograph of sannhemp mosaic virus shadowed with gold is reproduced herewith. A drop of the solution of crystalline virus in sterile water was dried on the collodion film mounted on the usual steel mesh. This was then shadowed with gold at angles ranging from $\tan^{-1}\frac{1}{5}$ to $\tan^{-1}\frac{1}{10}$. Several micrographs have been made of such shadowed specimens, and that reproduced is typical. This is a negative print: shadows are dark and the virus particles appear white. These electron micrographs seem to indicate that this virus consists of spherical particles. The measured diameter of the spherical particles varies from 40 to 26 mμ, the majority having a diameter close to 33 mμ. Further work is in progress.



Electron micrograph of shadowed sannhemp virus at a magnification of 38,000 diameters

The size and shape of different plant viruses crystallized so far are shown in the accompanying table for purposes of comparison.

Virus	Shape	Approximate size
Tobacco mosaic (ref. 6)	Rod	15 mμ × 300 mμ
Tomato bushy stunt (ref. 7)	Spherical	26 mμ
Tobacco necrosis (ref. 7)	,,	20 mμ
Southern bean mosaic (ref. 8)	,,	26 mμ
Squash mosaic (ref. 9)	,,	30 mμ
Turnip yellow mosaic (ref. 10)	,,	22 mμ
Sannhemp mosaic	,,	33 mμ

Thanks are due to Prof. M. N. Saha and Dr. J. N. Mukherji for their interest in the work, and to the Ministry of Education, Government of India, for supporting this investigation.

Isolation of 17-Hydroxycorticosterone and 17-Hydroxy-11-dehydrocorticosterone from Hog Adrenals

THE isolation of 17-hydroxycorticosterone and 17-hydroxy-11-dehydrocorticosterone from hog adrenals has been described by Kuizenga *et al.*[1,2]. The method described involved many stages and an extensive series of benzene–water partitions to effect the separation and isolation of these compounds, the fractionation being followed by means of biological assays.

In this communication we wish to report a simplified method for the preparation of concentrates of these compounds from hog adrenals, involving only four stages, and for the isolation of these compounds from such concentrates by a simple chromatographic technique, giving yields higher than those previously recorded. The following details describe a typical experiment.

33 kgm. of frozen hog adrenals was minced into 66 litres of 99 per cent acetone and extracted by stirring for several hours. After filtration, and re-extraction with 66 litres of 80 per cent v/v aqueous acetone, the acetone extracts were bulked and concentrated *in vacuo*, below 40° C., to remove most of the acetone. The aqueous concentrate was successively extracted with three half-volumes of petroleum ether (60–80°) to remove the fatty material and finally with three one-volumes of chloroform B.P. The chloroform, after drying over anhydrous sodium sulphate, was concentrated to dryness, *in vacuo*, giving 11 gm. of a thick oily extract.

35 gm. of purified wood pulp ('Solka-flok') was impregnated with propylene glycol by immersing the pulp in a 25 per cent v/v propylene glycol/chloroform mixture, filtering the pulp on a Buchner filter and allowing it to dry in the air to remove the chloroform. The pulp was then dry-packed into a chromatographic tube, 35 cm. long × 3 cm. diameter. The 11 gm. of concentrate was mixed with untreated wood pulp and the mixture packed on top of the column. Elution of the column was effected by means of toluene and 100-ml. fractions were taken. An aliquot of each fraction was taken after concentration *in vacuo* and run on paper strip chromatograms as described by Zaffaroni *et al.*[3]. An improved method of impregnating the paper strips with propylene glycol is to soak the strips in a 25 per cent v/v propylene glycol/chloroform mixture and then allow them to dry in air to remove the chloroform and give an even distribution of the propylene glycol on the strip. Control strips were prepared with 17-hydroxycorticosterone and 17-hydroxy-11-dehydrocorticosterone to act as markers and to permit an estimation to be made of the quantities of the compounds present. The bulk of the extract containing fatty material came through the column in the early fractions and contained no detectable amounts of 17-hydroxycorticosterone or 17-hydroxy-11-dehydrocorticosterone. The fractions containing these compounds were united and concentrated to dryness *in vacuo*. The concentrate was dissolved in a small volume of carbon tetrachloride and three volumes of petroleum ether (60–80°) added. The insoluble precipitate produced, weight 151 mgm., was found to contain substantially the whole of the 17-hydroxycorticosterone and 17-hydroxy-11-dehydrocorticosterone present in the original concentrate put on the column.

The crude material was redissolved in chloroform and the solution applied as a narrow band to two sheets of filter paper, 9 in. square, previously impregnated with propylene glycol. The sheets were transferred to a chromatographic tank, using toluene as the mobile phase. The positions of the respective bands were determined by cutting out a narrow lengthwise strip of paper and spraying with ammoniacal silver nitrate solution or iodine solution. Strips corresponding to these bands were cut across the paper sheets and eluted with chloroform, the solution being washed with water to remove the glycol, dried to remove traces of water and finally concentrated *in vacuo*. 11 mgm. of 17-hydroxycorticosterone and 97 mgm. of 17-hydroxy-11-dehydrocorticosterone were obtained, their identity being proved by the usual means, including infra-red spectroscopy.

Attempts were made to convert other steroids present in the cortical extract, in particular, those in the fast-running fractions from the column described above, into 17-hydroxycorticosterone or 17-hydroxy-11-dehydrocorticosterone by incubating at 37° C. with preparations of adrenal tissue under a variety of conditions. No evidence of such biosynthesis was obtained. Our experience in this connexion leads us to support the view that only 17-hydroxy-11-desoxycorticosterone (Reichstein's *S*), which appears to be present in the cortex in minute quantities, is converted by adrenal enzymes into 17-hydroxycorticosterone and 17-hydroxy-11-dehydrocorticosterone.

This chromatographic method of isolation can be effectively applied to urine extracts. With urine extracts, however, two other unidentified bands reacting with the ammoniacal silver nitrate are obtained, one near the origin and the other in front of the 17-hydroxy-11-dehydrocorticosterone.

Nature of the Factor in Soil-extract Responsible for Bacterial Growth-stimulation

Soil-extract is a valuable constituent of media for the growth of many soil bacteria. A medium containing only agar and aqueous soil-extract will give much higher plate counts from soil than any other medium in common use. Lochhead and Chase[1] showed that one-third of the bacterial cultures isolated from soil in soil-extract agar were unable to grow in a liquid medium containing a wide selection of amino-acids and vitamins, unless soil-extract was also added. They tentatively concluded that several different growth-promoting substances were involved. Some work on the nature of the soil-extract effect is briefly summarized here.

Dilution plates (1 : 500,000) were made from various soils in an agar medium containing soil-extract (25 per cent), peptone (0·05 per cent) and yeast-extract (0·05 per cent). Many of the cultures obtained from colonies on these plates would not grow initially in a casein–salts–vitamins medium, but a large proportion grew, either initially or eventually on subculture, in a medium containing 0·5 per cent peptone (Difco 'Tryptone') and 0·3 per cent yeast-extract (Difco). A number of cultures would not grow in this medium, or in several others tested, including that of Proom and Woiwod[2], but vigorous growth was obtained in the 'Tryptone' – yeast-extract medium if it were supplemented with aqueous soil-extract. Several of these cultures have been used as test organisms in the work now to be described.

Extracts of a number of Hertfordshire soils, prepared by autoclaving (15 lb./in.^{2} for 1 hr.) equal weights of soil and distilled water, were all active when added to the basal 'Tryptone' – yeast-extract medium in 25 per cent concentration. Acetone or alcohol extracts were inactive. Extracts made with sodium hydroxide (0·1 or 0·01 N) were inactive; but extracts made by autoclaving or refluxing the soil with 0·3 per cent hydrochloric acid were highly active. Sulphuric acid extracts were usually inactive. Soil from untreated and farmyard manured plots in Broadbalk field, Rothamsted Experimental Station, were compared by the hydrochloric acid method of extraction; both soils gave active extracts, 0·5–1·0 per cent in the medium being sufficient to give good growth of all test organisms. Water or hydrochloric acid extracts of a number of acid heath soils were inactive.

Treatment of active extracts with cation-removing base-exchange materials ('Soucol', 'ZeoKarbs 215' and '216') removed activity; treatment with 'De-acidite' or charcoal had no effect. If sodium hydroxide were added, the solution heated and the resultant precipitate removed, all activity disappeared. If the extract were evaporated to dryness, the active material could be taken up from the residue by water but not by ether. Water extracts of the dry residue ashed by fusion or with concentrated sulphuric acid were inactive, but extracts of the residue after wet ashing with perchloric acid were active. On the basis of these results, a number of likely ash constituents were tested and it was found that calcium chloride would replace the soil-extract. If the calcium chloride were added to the basal medium before autoclaving, results were frequently unsatisfactory, but if sterilized separately and mixed with the sterile peptone – yeast-extract medium, good growth was always obtained. Experiments with various test organisms indicated that minimal requirements of calcium chloride varied from 2·5 to 50 p.p.m. All soluble salts of calcium tested were effective. Strontium could replace calcium with all cultures; magnesium replaced calcium with some cultures. It seems likely that one or more of these cations are responsible for the effect of soil-extract.

The amount of calcium supplement required to allow growth in a 'Tryptone' – yeast-extract medium is related to the concentration of 'Tryptone' (see table). This suggests that the calcium may not be acting as a simple nutrient but may more probably be acting as an antagonist to some toxic substance present in the peptone. This view is supported by the discovery that different brands of peptone require different concentrations of supplementary calcium to promote growth.

The exacting organisms used in this work are Gram-negative; they appear to be plump rods when studied in heat-fixed films or chains of banded rods when stained in acid Giemsa. Growth is slow bu substantial on nutrient agar; if the agar is replace by silica-gel, growth is negligible. No growth take place in liquid media unless soil-extract or the cation mentioned above are added. Some cultures ar pigmented.

Growth of three cultures after 12 days at 25° C. in media containing 0·3-per cent yeast-extract and varying concentrations of 'Tryptone' and calcium chloride (+++ = vigorous growth; ++ = moderate growth; + = slight growth, – = no growth)

Multiple Infection of Clover Plants by Strains of the Nodule Organism in the Field

The possibility of obtaining, under experimental conditions, a simultaneous association of a leguminous plant with different strains of the nodule organism has been investigated by previous workers, with somewhat varying results[1]. So far as I am aware, the only published observations of multiple infection of a given legume plant in the field by strains of the nodule organism of different nitrogen-fixing powers are those included in the recent paper by Purchase and Vincent[2] which refer to clover plants under Australian conditions. Prior to the publication of this paper, I had begun an investigation of this aspect in clover plants growing in the west of Scotland.

A detailed study has been made of the strains of the nodule organism associated with six plants of red clover taken from hill-farm land near Aberfoyle, Perthshire, ten isolations of the organism being made from each plant, from different nodules. The effectiveness of these isolations in nitrogen fixation was tested on plants of red clover grown in aseptic culture in test-tubes containing an agar rooting-medium free from added combined nitrogen. The detailed procedure was similar to that described by Bond and McGonagle[3], except that the effectiveness of the isolations was assessed by comparison with a standard effective strain, taking the dry weight attained by plants as the basis for assessment. Isolations producing plants having a dry weight of not less than seventy per cent of that of the standard plants were classed as effective, those producing plants of dry weight not exceeding twenty per cent of that of standard plants were classed as ineffective and the remainder were classed as intermediate.

After statistical treatment of the data there is clear indication that each of the plants examined had associated with it at least two strains of the nodule organism, usually an effective and an ineffective type. In three plants there were possibly three or four strains present, differing in their powers of nitrogen fixation. Further investigations are being made to determine whether this multiple infection is prevalent in legumes in the field. If this is confirmed, it will help to explain the observation (by Dr. G. Bond) that when isolations of the nodule organism are made from single nodules from each of a number of clover plants growing in a given area, although both effective and ineffective strains may be obtained, the plants yielding the latter show no very marked difference in nitrogen status from those yielding effective strains. To some extent this can be explained by the fact that under field conditions the plant is not entirely dependent on the nodules for its nitrogen nutrition. In addition, as a result of multiple infection, in a particular area, the proportion of nodules produced by effective and ineffective strains may tend to be similar on all plants, resulting in fairly uniform vigour.

It may be of interest that some of the effectiveness tests were carried out during the winter months, the natural light then available being supplemented with artificial light from a battery of 'daylight' fluorescent tubes arranged as described by Low[4]. The intensity of the artificial light alone at plant-level (12 cm. below the fluorescent tubes) was approximately 300 ft. candles, the light being supplied for sixteen hours each day. Very satisfactory growth was obtained under these conditions, the dry weight attained by the plants being only slightly inferior to that of plants grown in summer.

I am indebted to Dr. G. Bond for his advice during the course of this investigation and to the Botany Department, University of Glasgow, for the use of the fluorescent lights.

Myxobacteria Mistaken for Nitrifying Bacteria

THE nitrifying bacteria, like the sulphur micro-organisms, have been studied almost entirely from a physiological aspect. With the exception of *Nitrosomonas* and *Nitrobacter*, the descriptions of the various genera have been copied from those given by the original investigators[1]. This has led to the description of nitrifying genera with the morphological characters of Myxobacteria, with which the cultures were, apparently, contaminated.

Although enrichment cultures similar to those originally devised by Winogradsky have been used by subsequent workers, only *Nitrosomonas* and *Nitrobacter* species have been isolated. The remaining five genera now listed[2], with the exception of *Nitrosocystis*, seem never to have been observed again. In my opinion, fruiting bodies of *Sorangium* were mistaken for colonies of nitrifying bacteria, and were described in the three genera, *Nitrosocystis*, *Nitrosogloea* and *Nitrocystis*.

The descriptions and photomicrographs by H. and S. Winogradsky show that these genera are almost identical with one another. All three form large aggregates composed of numerous cysts. In some of the species, the cysts appear to be surrounded by a small sheath; but in every case they are composed of numerous, tightly packed, spherical or oval resting cells. This appearance is identical with that observed in *Sorangium* species.

Similarly, Winogradsky's photomicrographs of stained preparations of the disintegrated cysts of these genera closely resemble the appearance in *Sorangium*. Each shows the peculiar bean-shaped or wedge-shaped, capsulated structures arranged in pairs or tetrads, when stained by classical methods. My own cytological observations on *Sorangium* show, however, that this appearance is due to the fact that the microcyst wall is not readily stained. The microcysts actually contain a central vesicular nucleus, and are spherical or slightly oval in shape. Comparison of the photomicrographs of living and stained preparations of *Nitrosogloea*, for example[3], show that this is also the case in the 'nitrifying' genera. The young cysts, photographed *in situ*, show tightly packed, spherical cells, which are not seen in the stained preparations.

The difficulties involved in obtaining pure cultures of nitrifying bacteria are well known. Although the inorganic medium prevents the growth of many micro-organisms, those Myxobacteria which are predatory on other bacteria could appear in the enrichment cultures. Examination for contaminants by the standard technique of inoculation into meat infusion broth fails to demonstrate their presence.

Winogradsky seems to have been unfamiliar with this group of the Myxobacteriales, because they are not mentioned in his soil studies[1]. The myxobacterial swarm is often difficult to detect, although the coloured fruiting bodies are visible to the naked eye.

Imsenecki has also suggested that *Nitrosocystis* is a species of *Sorangium* and has demonstrated that these Myxobacteria are common contaminants on cultures of nitrifying bacteria[4].

Nitrosocystis has been regarded by some workers[5,6] as a hard-colony variant of *Nitrosomonas*. In one instance[5], there is no evidence that the cultures employed were pure, and in the other[6] the brief description of the hard colonies in no way resembles the original descriptions of *Nitrosocystis*.

It would seem, therefore, to be almost certain that three of the genera of nitrifying bacteria now listed are invalid. They were, in fact, Myxobacteria of the genus *Sorangium* which were contaminating the cultures of *Nitrosomonas*.

Microbiological Oxidation of Ammonium and Thiocyanate Ions in Soil

AMMONIUM sulphate[1] and sodium thiocyanate[2], when perfused through chalked soils neutralized by calcium carbonate, are metabolized by the growth of specific groups of soil microflora on the soil crumb surface to nitrate and ammonium sulphate respectively.

Thiocyanate is a known inhibitor of bacterial growth and poison[3,4] and is frequently found in sewage wastes. It has been reported to be highly toxic to the nitrification micro-organisms[5]. This inhibitory influence on the growth of the nitrifying micro-organisms in soil has been confirmed using the Audus modification[6] of the original soil perfusion technique[7].

Thiocyanate at a high concentration of 0·01 *M* when perfused through an enriched nitrifying soil has been found, however, to have only a partially inhibitive influence on the oxidation of ammonium sulphate, inhibiting the oxidation of ammonium-nitrogen to nitrite-nitrogen by 24 per cent and nitrite-nitrogen to nitrate-nitrogen by 62 per cent (see table). This is of interest, as it has been reported[1] that other sulphur compounds, thiourea and methionine, are highly toxic to the nitrification process.

20 gm. soil 1–4 mm. + 0 5 gm. precipitated chalk perfused with 200 ml. solution	After two days perfusion		
	Nitrite-nitrogen (µgm./ml.)	Nitrate-nitrogen (µgm./ml.)	Total nitrogen (µgm./ml.)
(1) Control, *N*/140 ammon. sulphate	0	100	100
(2) Control + *M*/100 sod. thiocyanate	38	38	76

The thiocyanate, after being perfused through a partially enriched nitrifying soil for four to five days, is metabolized to ammonium sulphate by a specific group of thiocyanate-oxidizing micro-organisms which grow in the soil, and it is thus possible to have a soil enriched with the three specific groups of soil microflora, the thiocyanate-oxidizing bacteria and the two groups of nitrifiers oxidizing ammonium ions and nitrite ions respectively. Using such a soil, it is possible to study the interrelationships of the three groups with respect to the utilization of their specific metabolites. Such a study has been made and the results are shown graphically in Figs. 1 and 2. The graphs demonstrate the biological oxidation of ammonium cations and thiocyanate anions in soil enriched with two groups, the nitrifiers, and soil enriched with the three groups, the nitrifiers and the thiocyanate oxidizing micro-organisms.

Using enriched nitrifying soils, ammonium cations are rapidly oxidized to nitrate, very little nitrite formation being observed (Fig. 1*a*), while thiocyanate (Fig. 1*b*), when perfused through a similar soil, is not metabolized until after a lag phase, when growth of its specific oxidizing micro-organisms takes place and the build-up of nitrite is observed, due to the oxidation by the nitrifying organisms already present in the soil of the ammonium cations formed.

When both groups are present (Fig. 2), ammonium cations are immediately metabolized to nitrite and to a lesser extent to nitrate. With the rapid growth of nitrate-forming micro-organisms, however, both ammonium cations and nitrite anions are rapidly metabolized to nitrate anions (Fig. 2*a*). Thiocyanate, when perfused (Fig. 2*b*), is immediately metabolized at a constant rate to ammonium sulphate, which in turn is metabolized via nitrite to nitrate as in Fig. 2*a*. These latter two oxidations are slightly inhibited until the thiocyanate is completely oxidized.

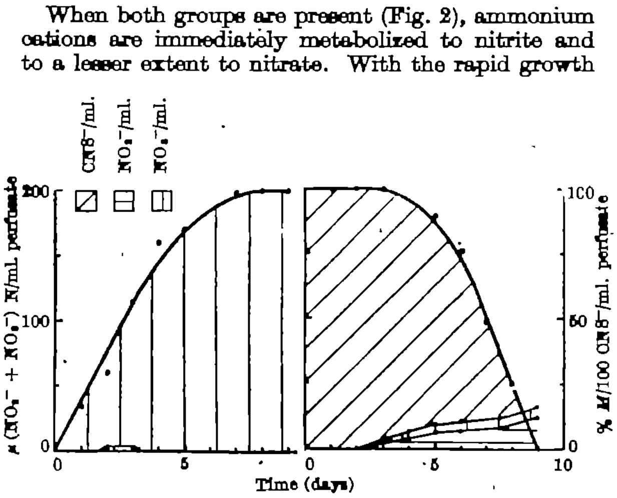

Fig. 1. 20 gm. soil (sieved, 1–4 mm.) + 0 5 gm. precipitated chalk. Enriched with nitrifying micro-organisms by previous perfusion with 200 ml. *N*/70 ammonium sulphate. Washed with distilled water and re-perfused with 200 ml. of (*a*) *N*/70 ammonium sulphate, and (*b*) *M*/100 sodium thiocyanate

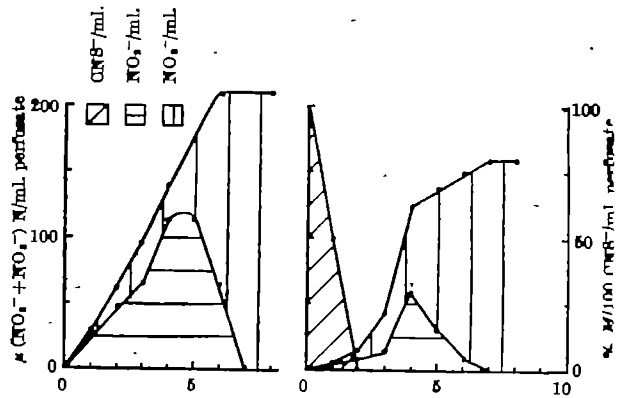

Fig. 2. 20 gm. soil (sieved, 1–4 mm.) + 0·5 gm. ppt. chalk. (Enriched with nitrifying and thiocyanate oxidizing micro-organisms by previous perfusion with 200 ml. *N*/70 ammonium sulphate and later perfusion with 200 ml. *M*/100 thiocyanate.) Washed with distilled water and re-perfused with 200 ml. of (*a*) *N*/70 ammonium sulphate and (*b*) *M*/100 sodium thiocyanate

Thus, the inhibitive effect of thiocyanate on nitrification in soil is not permanent, and it is more toxic to the nitrate forming organisms than to the nitrite-forming group. The exact nature of its action is unknown. The experiments emphasize the usefulness of the soil perfusion technique in the study of dynamic biochemical processes occurring in the soil, and in the study of interrelationships of specific groups of micro-organisms as they occur in Nature.

A Pronounced Sex Difference in Recombination Values in the Sixth Chromosome of the House Mouse

The loci *be* (belted), *Ca* (Caracul), and *N* (naked) constituting the sixth linkage group in *Mus musculus* are closely linked and in the order *be*—*Ca*—*N*. Linkage of *Ca* and *N* was established by Cooper[1]. He obtained the recombination values 2·64 per cent in males and 0 per cent in females, the difference not being significant on the total number of mice bred (335). Murray and Snell[2] discovered the factor *be* and established the order *be*—*Ca*—*N*. On combining their own data with those of Cooper, they obtained a significant sex difference (probability 0·043) for the segment *Ca*—*N*, there being 12 recombinants out of 392 mice bred from backcrossed heterozygous males, while no recombinants were found among 158 mice bred from heterozygous females. For the segment *be*—*Ca* they obtained the recombination value 11·49 per cent, with no significant difference between the sexes.

In 1947 the genes *be* and *Ca* were introduced into tocks existing in this Department by means of mice sent by Dr. Snell from the Jackson Laboratory, and were combined with *N* in various associations. In 1949 I set up three-point backcross matings in order o redetermine the linkages simultaneously in the two segments and to investigate further the sex differences in the recombination frequencies. The experiment is still in progress, but the data so far accumulated exhibit a marked excess of recombination in the males over the *be*—*Ca* segment, and confirm the earlier indications in the *Ca*—*N* segment.

The backcrosses are of four types, *A*, *B*, *C* and *D*, n which the homozygous parents are *be*++/*be*++, and the heterozygous parents are respectively:

(*A*) +*Ca N*/*be*++ (*B*) *be Ca N*/+++
(*C*) *be*+*N*/+*Ca*+ (*D*) ++*N*/*be Ca*+.

All types (except *A*, where male matings have not yet been set up) comprise matings both of female heterozygotes and male heterozygotes. It is proposed to achieve balancing between males and females as the experiment proceeds. The recombinant offspring of each type of mating fall into three classes, (1), (2) and (1,2), corresponding respectively to recombination in *be*—*Ca* only, to recombination in *Ca*—*N* only, and to simultaneous recombination in both segments. Table 1 shows the numbers in each class observed out of a total of 1,053 mice bred to date.

Table 1

Mating type	Female parent heterozygous (1)	(2)	(1,2)	Bred	Male parent heterozygous (1)	(2)	(1,2)	Bred
A	1	1	0	27	—	—	—	—
B	0	2	0	80	26	6	0	204
C	3	0	1	32	18	4	0	133
D	10	2	0	256	29	8	0	321
Totals	14	5	1	395	73	18	0	658

The observed percentage recombination values for the three segments *be*—*Ca*, *Ca*—*N* and *be*—*N* are thus as given in Table 2.

Table 2

	be—*Ca*	*Ca*—*N*	*be*—*N*
In females	3·80	1 52	4·81 per cent
In males	11·09	2 74	13·83 per cent

A χ_1^2 test applied to the four-fold tables for *be*—*Ca* confirms that the marked difference between the sexes in recombination frequency over *be*—*Ca* is significant at a level more extreme than 0·001 ($\chi_1^2 = 17·2$).

On the number of mice bred, the difference for the short segment *Ca*—*N* is not yet significant ($\chi_1^2 = 1·64$). However, when the new data for this segment are combined with those of Cooper and those of Murray and Snell, significance is achieved with a χ_1^2 equal to 5·18.

It is interesting to contrast the present situation in which two adjacent segments show the same property —recombination more frequent in the male—with that obtaining in the *A*—*un*—*we*—*pa* region of the fifth chromosome. Table 3 shows the results of a four-point backcross experiment (still in progress in this Department), which Prof. R. A. Fisher and Dr. A. R. G. Owen have kindly made available to me.

Table 3

	A—*un*	*un*—*we*	*we*—*pa*	Bred
Recombination in females	4·44	7·29	4 05 per cent	2,502
In males	4·43	4·42	2·39 per cent	2,263

Here the adjoining segments *un*—*we* and *we*—*pa* show a sex difference which is in favour of the female, in contrast to the position in the sixth chromosome. Moreover, the adjoining segments *A*—*un* and *un*—*we* exhibit a notable discontinuity in behaviour. The sex difference is marked and significant in *un*—*we* but entirely absent in *A*—*un*.

Effect of Ascorbic Acid on Skin Permeability in Adrenalectomized Rats

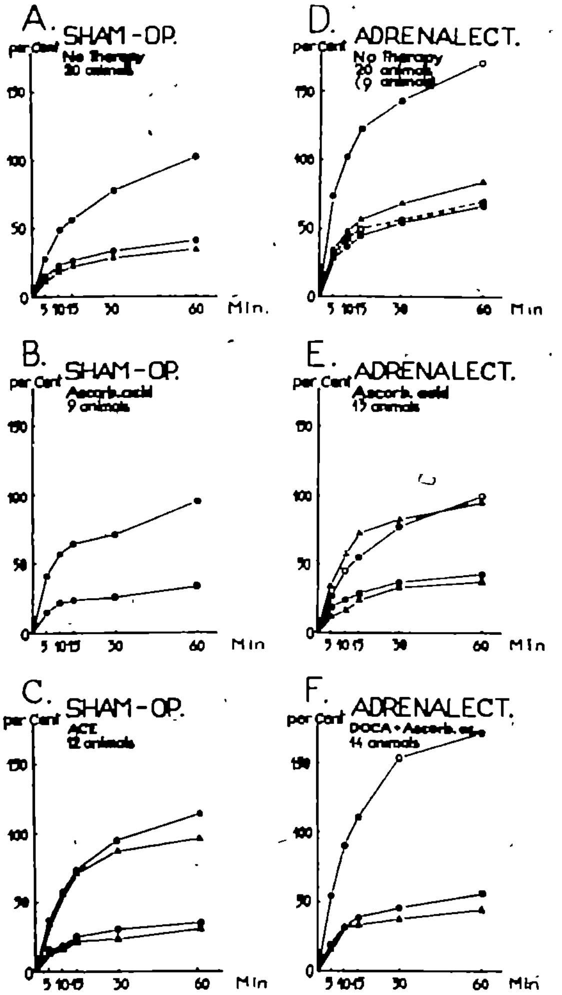
In recent years, facts have accumulated about the composition of the ground substance of the connective tissue proper. In loose connective tissue, this amorphous matrix consists of a highly viscous gel built up by acid mucopolysaccharides like hyaluronic acid and mucoitin sulphuric acid. The ground substance obviously is a very labile structure in respect of its physical and chemical composition. Among the agents that may have an influence on the composition of the interfibrillar gel, the adrenocortical hormones and ascorbic acid have attracted much attention.

With the aid of the spreading technique applied to dermal connective tissue of rabbits and mice, Opsahl *et al.*[1-3] have reported experimental results of a significant enhancing effect of adrenalectomy on the rate of spread of india ink in the skin of living animals. They were also able to show that adrenocortical extract restricted the spreading in intact animals. Animals exposed to a moderate stress likewise showed a restriction of dermal spreading, possibly due to a physiological effect of the adrenocortex hormone.

Several workers have ascribed an important role to ascorbic acid in the metabolism of the ground substance of connective tissues. Thus, restricted production of metachromatic substance in connective tissue of scorbutic animals is reported by various investigators[4,5]. So far as we know, no spreading tests have hitherto been performed for studying the effect of ascorbic acid in connexion with adrenal steroids.

In the course of investigations of hormonal effects on the ground substance of loose connective tissue, we have carried out experiments with a standardized spreading technique on adrenalectomized rats given deoxycorticosterone acetate and ascorbic acid as substitution therapy. Some preliminary results from these experiments are reported in this communication.

In our investigations the rate of dermal spreading of Evans blue and hæmoglobin was studied in the skin of living anæsthetized rats, and in skin flaps cut out from the same animals and injected supravitally. The results are shown in the accompanying diagrams. The pronounced increase of the spreading rate in the adrenalectomized rats is clearly shown in *D* when compared with the sham-operated controls (*A*). These results were obtained both in living skin and



Dermal spreading rate within one hour after injection of 0·10 ml. indicator solution (○●, Evans blue; △▲, hæmoglobin). The areas of the weals were calculated as regular ellipses.

—○—○—, —△—△— } weals in living skin *in situ*

—●—●—, —▲—▲— } weals in cut-out skin-flaps ('dead skin')

- - - ○ - - - ○ - - -, 9 animals tested 6 hr. after adrenalectomy. ACE = adrenocortical extract; DOCA = deoxycorticosterone acetate. Ordinates, percentage increase in weals; abscissæ, time after injection of indicators

'dead' skin six days after the operation. When, however, the spreading rate was measured within a short time after the operation (in this case six hours) no such effect of the operation was demonstrable in living skin (*D*, dotted line). This is presumably due to a stress effect of the anæsthesia and the operation, both of which may induce an output of adrenocorticotrophic hormone and thus of corticosteroids.

Ascorbic acid and deoxycorticosterone acetate, used in the clinic as substitutes for cortisone[6], were given together (*F*) in order to find out whether these substances had any effect on the spreading rate. The dosages used were 1 mgm. deoxycorticosterone acetate and 10 mgm. ascorbic acid per day administered intramuscularly. As a control, 10 mgm. ascorbic acid alone was administered both to sham-operated (*B*) and to adrenalectomized animals (*E*). Another group of intact, sham-operated animals was givén 0·1 ml. adrenocortical extract per day (corresponding to 5 gm. cortex substance) intraperitoneally. The injections were started in immediate connexion with the operations, and continued with one injection every day until the spreading test on the sixth day after operation. This scheme was followed with all the groups except for the one tested six hours after adrenalectomy (*D*, dotted line).

The administration of ascorbic acid only (*E*) had a rather unexpected effect. The dose given seems to inhibit the 'barrier-breaking' effect of the adrenalectomy entirely. The animals given ascorbic acid thus showed the same rate of spreading as the sham-operated, untreated controls (*A*). Furthermore, this effect is valid for both living skin *in situ* and 'dead' skin flaps. Any important effect on the circulation can thus be ruled out. The combined treatment with deoxycorticosterone acetate and ascorbic acid has a rather small effect on 'dead' skin and none at all on living skin (*F*). In the sham-operated animals neither ascorbic acid (*B*) nor adrenocortical extract (*C*) showed any effect on the spreading.

The results given here do not offer any definite explanation of the peculiar effect of ascorbic acid on adrenalectomized rats. It is supposed by some workers[7] that the effect of adrenocortical hormones on the ground substance of connective tissue primarily concerns the activity of hyaluronidase present in the tissue. The ascorbic acid may act as an inhibitor of the hyaluronidase, which is possibly activated in animals deprived of their adrenals. Such an inhibiting effect of ascorbic acid can be demonstrated *in vitro*.

These investigations are being continued, and a detailed description will appear elsewhere.

Antigens in the Developing Newt Embryo

IMMUNE sera have been prepared in rabbits against isolated tissues of stages of embryonic *Triton alpestris*. The tissues used were: whole gastrula (crescent-shaped blastopore), archenteron roof, and ectoderm (both from early yolk-plug stages). The antisera were used both for interfacial precipitin tests and, diluted, as stock culture media of the same osmotic pressure as Holtfreter's solution; these media contained 1 : 5 to 1 : 20 parts of serum.

The experiments have involved the dissection of some six thousand embryos; but as most of the material has to be used for preparing immune sera or for absorption, the number of explants cultured is not as large as would be wished, and it seems best to sum the results from the two seasons 1949 and 1950; tests show that the figures of deaths and survivals for these years may be considered to come from the same sample.

A total of 579 explants were set up. The results in some of the classes are as follows. Of 104 explants into untreated antisera, 82 died within 48 hours (the majority within 36); of 64 in normal serum, 12 died within the same period; of 29 gastrulæ in anti-gastrula serum, 19 died, and 4 showed defective development; of 24 in anti-gastrula serum absorbed with blastulæ, 17 died, 3 showed inhibited development; 1 in 21 and 1 in 7 died in, respectively, normal serum and normal serum plus blastula extract; of 28 morulæ in anti-gastrula serum, 25 died—2 as gastrulæ of inhibited development—the remaining 3 developed normally; and of 33 morulæ in anti-gastrula serum absorbed with blastula, 18 died, 11 showed inhibition of growth (2 of these survived for more than 48 hours), and 4 were unaffected.

Those classed as exhibiting inhibition of growth remained in general large-celled, with the blastopore forming a slight depression or small pit; in some cases, a dorsal lip was produced which bulged outwards, but there were no lateral lips. The dorsal lip did not appear to be invaginated for any distance.

These figures suggest the appearance of an antigen or antigens at or during gastrulation.

Turning to explants from the late gastrula: of 42 explants of archenteron or ectoderm into both anti-archenteron and anti-ectoderm antisera, 33 died; of 23 explants into control serum, 10 died; of 17 explants* into homologous antiserum absorbed with heterologous tissue, 14 died; and of 17 explants into heterologous antiserum absorbed with homologous tissue, 8 died.

These figures suggest the possibility that archenteron and ectoderm contain one or more antigens in common, but also one or more specific to each.

This season it is hoped to continue the study of the origin of new antigens and their subsequent fates by testing these two antisera with antecedent tissues (blastula ectoderm) and subsequent derivatives (for example, neural plate and neurula ectoderm) after appropriate absorptions.

A full account will be published elsewhere.

Estimation of Radioactive Hydrogen as Tritiobutane in the Geiger Counter

A METHOD for the assay of tritium has been described by White, Campbell and Payne[1], who convert radioactive water into methane by means of aluminium carbide and then 'count' the methane in the proportional counter. Since this method necessitates additional proportional electronic equipment, I have found it more convenient to assay tritium in the form of radioactive butane, which can be 'counted' in the Geiger region and which, moreover, being condensable at liquid air temperature, is easily manipulated in a vacuum system.

Half the hydrogen of water can, of course, be incorporated into a selected hydrocarbon by reaction with the appropriate Grignard reagent. Butane was chosen in this case because Powell and Reid[2], in their work on the isomerization of butanes, actually prepared tritiobutane and reported it to be a good counter gas.

As carbon-14 is usually assayed in this Department by means of an internal beta-counter with graphite cathode and Neher–Harper quench circuit, this was the equipment first used for testing the properties of butane as a counter gas. At a pressure of 14 cm. mercury, some counters of this pattern show a well-defined Geiger region and a long, flat plateau; but as the proportion doing so is only about one in five, others, with passive iron cathodes, were tried. Of these a much higher proportion have a good characteristic provided the cathode is thoroughly outgassed; but some selection is still necessary. A good counter of this type (20th Century *GA*. 10*M*) containing *n*-butane at a pressure of 14 cm. mercury has a starting voltage of 3,000 volts and a plateau extending over 800 volts with negligible slope. External quenching appears to be essential.

At this pressure the counter contains about 12 standard millilitres of gas, which is the volume of butane theoretically obtainable from the action of 10 mgm. water on the Grignard reagent. As 10 mgm. is about the amount of water obtained from the combustion of convenient quantities of biological materials, a method for the conversion of water to butane on the 10 mgm. scale has been developed.

About 1·5 ml. of a freshly prepared 2*N* ethereal solution of *n*-butyl magnesium bromide is pipetted rapidly into a 10-ml. tube fitted with a *B*-10 standard socket. The tube is plugged on to a *B*-10 cone beneath a stopcock connected with the high-vacuum system, both joint and stopcock being lubricated with silicone grease. The total space beneath the stopcock is about 15 ml. The ether is removed from the Grignard reagent by distillation *in vacuo* with gentle warming. The whole tube is then baked out for two hours at 120°–130° on open pumps. This removes the last traces of ether which would otherwise dilute the butane formed at the next stage. A blank determination carried out by heating the reagent so prepared for an hour at 120° with the stopcock closed should yield no more than 150 µl. of gas.

The tube is allowed to cool and 10–20 mgm. of radioactive water condensed into it by means of liquid air. The tap is closed and the tube heated at 120°–130° for an hour. Tritiobutane is produced almost quantitatively (90–95 per cent of theoretical yield). It is purified by distilling through a *U*-tube cooled to − 78°. A suitable aliquot is measured out, condensed into the counter and the pressure adjusted to 14 cm. with inactive butane. Radioactive butane has not been found to contaminate the counter and a constant background counting-rate is observed between assays.

The method has been checked by assaying a stock solution of radioactive water (containing about 2 µC. per ml.) and various dilutions of it. The specific activity of the butane prepared from these various dilutions was, within experimental error, proportional to the dilution. This indicates that at these tritium concentrations no isotopic separation occurs during the reaction.

The accompanying table shows the results obtained when these samples of radioactive water were assayed. The calculated specific activity shown for each sample in column 5 is based upon the experimentally determined activity of the stock solution itself.

Water sample (% stock)	Vol. butane assayed (ml.)	Activity (c.p.m.)	Specific activity (c.p.m. per ml.)		Error (per cent)
			Obs.	Calc.	
10	8·85	1,353	153	153	0

It would obviously be an advantage if a large excess of dry Grignard reagent could be prepared and then used several times. Unfortunately, it has been found that the butane produced by the action of a second sample of water on a once-used tube of reagent is contaminated by radioactivity from the first sample. This may be due to the fact that the yield is never quite quantitative. Furthermore, the yield on the second occasion is considerably reduced. However, using fresh reagent for each experiment, the method can be conveniently applied to routine tritium assays. The tubes of reagent are prepared in batches of six and baked out together on a manifold prior to use.

Thanks are due to the Calor Gas Company for supplying pure *n*-butane, and to 20th Century Electronics for their very helpful co-operation in designing and selecting counters.

Solution of the Thomas–Fermi–Dirac Equation

The fundamental equation of the Thomas–Fermi–Dirac statistical atom model[1] is the so-called Thomas–Fermi–Dirac equation

$$\psi'' = x\left[\left(\frac{\psi}{x}\right)^{1/2} + \beta\right]^3, \tag{1}$$

where ψ'' denotes the second derivative of ψ by x, β represents the constant $\beta = 3^{1/3}/(32^{1/3}\pi^{2/3}Z^{2/3})$ and Z the atomic number. This equation was solved by Umeda[2] for all neutral atoms with the boundary conditions derived by Brillouin[3]:

$$\psi(0) = 1, \quad \psi(x_0) = 0, \quad \psi'(x_0) = 0, \tag{2}$$

where x_0 corresponds to the border of the atom. The second and the third boundary conditions are equivalent to the minimization of the energy of any single electron in the statistical atom. This requirement and the boundary conditions resulting from it are, however—as has been already mentioned by Jensen[4]—not in agreement with the statistical point of view, according to which the *total* energy of the statistical atom has to be a minimum, which is not equivalent to the minimization of the energy of the single electrons.

From the minimum-principle of the total energy of the neutral statistical atom, the following boundary conditions are obtained:

$$\psi(0) = 1, \; \psi(x_0) = \frac{\beta^2}{16}x_0, \; x_0\psi'(x_0) - \psi(x_0) = 0. \tag{3}$$

It can be seen easily that the solutions obtained by these boundary conditions differ only at the outer parts of the atom from the solutions of Umeda, and even there only to a small extent. The solution of the Thomas–Fermi–Dirac equation with the boundary conditions (3) may therefore be determined from Umeda's solutions in the following way. The solution is put into the form:

$$\psi(x) = \psi_u(x) + k\varepsilon(x), \tag{4}$$

where ψ_u denotes the solution of Umeda and $k\varepsilon$ is small compared to ψ_u. By k we denote a numerical factor independent of x. Putting this expression into (1) and expanding the right-hand side in terms of powers of $k\varepsilon$, one obtains for ε, by neglecting the terms of second and higher powers of $k\varepsilon$, the linear differential equation

$$\varepsilon'' = \frac{3}{2}\left[\left(\frac{\psi_u}{x}\right)^{1/4} + \beta\left(\frac{x}{\psi_u}\right)^{1/4}\right]^2 \varepsilon. \tag{5}$$

Singularities apart from $x = 0$ do not appear here, because the solution is of interest only between $x = 0$ and $x = x_0$, and the solution ψ_u disappears only at Umeda's x_0; this is larger than our x_0, which is determined here with the boundary conditions (3).

If one solves this equation with the boundary conditions

$$\varepsilon(0) = 0, \qquad \varepsilon'(0) = 1 \tag{6}$$

the first of the boundary conditions (3) is fulfilled and also it follows that the constant k determines the initial slope of ψ, for it is:

$$\psi'(0) = \psi'_u(0) + k. \tag{7}$$

The constants k and x_0 are determined from the second and the third boundary conditions (3). These calculations can be extended also to positive ions and spherical symmetrically compressed atoms.

The calculations are very simple and have been carried out by us for the atoms neon ($Z = 10$), argon ($Z = 18$), krypton ($Z = 36$), xenon ($Z = 54$) and radon ($Z = 86$), and for the single and double positive ions of these atoms. The tabulated solutions as well as the values of k and x_0 will soon be published in the *Acta Physica Hungarica*. By interpolation, solutions for further atoms can be obtained. The deviation of our solutions for argon, krypton and xenon from the exact solutions computed numerically by Jensen, Meyer-Gossler and Rohde[5] is less than 2 per cent.

We should like to express our thanks to Prof. Kwai Umeda for his kindness in having sent us his tabulated solutions.

Decomposition of Formic Acid by Periodate

Since the introduction of periodic acid as a reagent for glycols[1], it has been widely employed for elucidating the constitution of many organic compounds[2]. In recent years valuable information has been obtained in the study of polysaccharides by oxidation with periodic acid[3]. Under suitable conditions, one molecule of formic acid is liberated from a non-reducing end-group, and two from a reducing end-group[4]. Determination of the formic acid set free may give an idea of the chain-length of a polysaccharide, while the consumption of periodate per repeating unit is useful in locating the position of hydroxyl groups therein. It is therefore necessary to know whether or not formic acid itself is attacked by the reagent under experimental conditions.

While oxidizing hemicellulose from jute fibre (a methoxyuronic acid–xylan complex) with a saturated aqueous solution of potassium periodate (*p*H 4·1) at ordinary temperature, it has recently been observed that the amount of periodate consumed per gram of the hemicellulose is never constant, but increases with time. In order to see if the formic acid thus liberated is decomposed by periodate, 'Analar' formic acid of varying strengths was treated with periodate solution in the same way as hemicellulose, and the amount of periodate present in the reaction mixture was determined periodically by titration with sodium arsenite in presence of sodium bicarbonate[5].

Table 1. AMOUNT OF *N*/10 SODIUM ARSENITE (C.C.) REQUIRED FOR 10 C.C. OF THE REACTION MIXTURE (POTASSIUM PERIODATE AND FORMIC ACID)

Time (hr.)	Strength of formic acid in the reaction mixture *N*/20	*N*/50	*N*/80	*N*/100
0	1·80	1·80	1·80	1·80
48	1 0	1·05	1·10	0·85
96	0·65	0·80	1·0	0·85
168	0·20	0·55	0·70	0·70
216	Nil	0·30	0 60	0·50
264	Nil	0 10	0·35	-0·25

In more dilute solutions, formic acid appears to be unaffected by periodate (vide Table 2). It seems necessary, therefore, to maintain a strength of *N*/500 (or less) for formic acid in the final reaction mixture while using unbuffered periodate for oxidation.

Table 2. AMOUNT OF *N*/10 SODIUM ARSENITE (C.C.) REQUIRED FOR 10 C.C. OF THE REACTION MIXTURE (POTASSIUM PERIODATE AND FORMIC ACID)

Time (hr.)	Strength of formic acid in the reaction mixture *N*/100	*N*/500	*N*/750	*N*/1,000
0	3·70	4·0	4·0	4·0
24	3·10	3·85	3·95	3·85
72	2·30	3·75	3·80	3·90
144	2·10	3·80	3·95	3·95

A practically constant value for the consumption of periodate per gram of the jute hemicellulose was obtained using the periodate in acid solution buffered at *p*H 3·09 with sodium acetate and hydrochloric acid.

In such a solution, formic acid of *N*/20–*N*/100 strength remains practically unaffected by periodate, as will be seen from Table 3.

Table 3. AMOUNT OF *N*/10 SODIUM ARSENITE (C.C.) REQUIRED FOR 10 C.C. OF THE REACTION MIXTURE (POTASSIUM PERIODATE AND FORMIC ACID) BUFFERED AT *p*H 3·09

Time (hr.)	Strength of formic acid in reaction mixture *N*/20	*N*/50	*N*/80	*N*/100
0	2 80	2·80	2·80	2·80
24	2 70	2·75	2·70	2·80
72	2·60	2·70	2·70	2·60
144	2·70	2·80	2·70	2·80
192	2 70	2 70	2·60	2·70
264	2 70	2·75	2·75	2·75

Iodine was set free whenever there was little or no periodate left in the system. It would appear, therefore, that potassium iodate is reduced by formic acid to iodide (which with iodate gives iodine in acid solution) in absence of periodate. This is supported by the fact that a saturated aqueous solution of potassium iodate at room temperature (31° C.) readily reacts with formic acid and sets free iodine; but in presence of potassium periodate it liberates no iodine. This is not apparently in agreement with the observation of Halsall, Hirst and Jones[6].

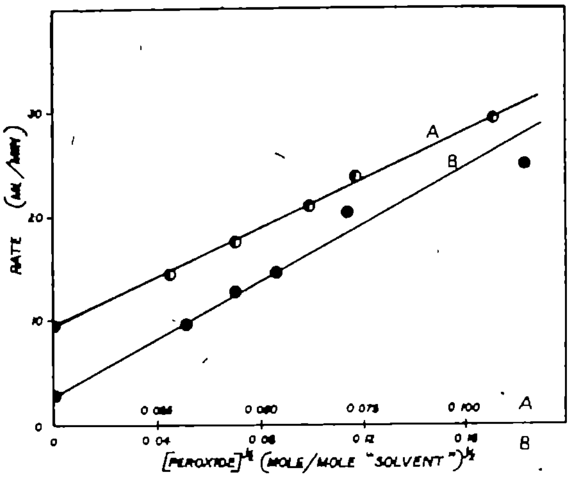
Mechanisms of Oxidation of Benzaldehyde

THE early work of Bäckström[1] demonstrated the chain character of both the photochemical and the 'thermal', that is, dark, oxidation of benzaldehyde to peroxide in the liquid phase. We have studied the kinetics of the thermal reaction in benzene solution at 31° C., and have found it to be catalysed by di-benzoyl peroxide. The increase in rate $\Delta\rho$ above that of the uncatalysed reaction ρ_0 is proportional to the square root of the concentration of dibenzoyl peroxide, as shown in the accompanying graph.



Variation of initial rate of oxidation of benzaldehyde in benzene solution with concentration of dissolved di-benzoyl peroxide at 31·0° C. and 620 mm. mercury oxygen pressure.
1 mole 'solvent' refers to 1 mole (benzaldehyde + benzene), that is, ($N_{\text{benzaldehyde}} + N_{\text{benzene}}$) = 1.
Curve *A*, $N_{\text{benzaldehyde}} = 0·224$; curve *B*, $N_{\text{benzaldehyde}} = 0·182$.
Rates are expressed in ml. oxygen (25° C., 760 mm. mercury)/min. mole 'solvent'

With constant concentration of di-benzoyl peroxide, the dependence of $\Delta\rho$ on both oxygen and benzaldehyde concentrations is such as is required by the mechanism shown by Bolland and collaborators[2] to occur in the peroxide-catalysed oxidation of olefines, namely:

$$\begin{array}{ll} Bz_2O_2 \rightarrow R^- & RO_2^- + RO_2^- \rightarrow \\ R^- + O_2 \rightarrow RO_2^- & R^- + R^- \rightarrow \\ RO_2^- + RH \rightarrow RO_2H + R^- & RO_2^- + R^- \rightarrow \end{array} \left.\vphantom{\begin{array}{l}a\\b\\c\end{array}}\right\} \text{Inactive products}$$

where $RH = C_6H_5CHO$.

The evidence leaves little doubt that the peroxide-initiated oxidation of benzaldehyde occurs by such a free-radical mechanism, the chains being terminated by mutual interaction of two radicals.

It is also clear, however, that the reaction which takes place in the absence of added peroxide (and of light) does not occur by this mechanism. This follows from the fact that the total rate of reaction in presence of di-benzoyl peroxide is given by:

$$\rho = \rho_0 + \Delta\rho = \rho_0 + \kappa[Bz_2O_2]^{1/2},$$

where ρ_0 is the rate of the peroxide-free reaction and κ is a constant for constant [RH] and [O_2] (see graph). If, on the other hand, the peroxide-free reaction occurred by the same mechanism as the peroxide-initiated reaction, the dependence of ρ on [Bz_2O_2] would be of the form

$$\rho = \kappa^1[\varphi + k[Bz_2O_2]\,]^{1/2},$$

φ being the (constant) rate of 'spontaneous' initiation, that is, of initial production of R^- or RO_2^- from benzaldehyde and oxygen, and k the specific rate of initiation by di-benzoyl peroxide. This is not the case. The peroxide-initiated reaction is therefore superimposed on the thermal reaction, which proceeds by a different chain mechanism.

In the presence of di-benzoyl peroxide, the oxidation of benzaldehyde thus takes place simultaneously by two distinct mechanisms. A similar result has been obtained by George[3] with tetralin containing di-benzoyl peroxide. It appears that, at least with benzaldehyde and tetralin, the occurrence of the free-radical mechanism set out above is dependent on the presence of decomposing peroxide, or of some other sufficiently energetic initiator[4].

A Simplified Coupled Filter System for Adsorption Chromatography

Hagdahl[1] has described an improvement in adsorption technique of Tiselius and Claesson[2], whereby much clearer fronts are obtained by the use of small filters which are easily packed. These can be coupled together by means of short distance-pieces with narrow bore which act as front straighteners. The parts of the column are entirely of stainless steel, which combines the necessary degree of rigidity with resistance to attack from solvents. It has, however, been found that in the presence of certain adsorbent materials such as carbon, such steel is not completely resistant to solutions buffered at very low pH.

A more reliable container for the adsorbent can be made from 'Perspex'. The mechanical properties of this material, however, do not lend themselves to the construction of column components which require repeated screwing and unscrewing. A simplified model has therefore been designed which combines all the advantages of Hagdahl's original apparatus with much greater ease of production and assembly. The filters made from 1-in. diameter 'Perspex' rod are a sliding fit into an external jacket of stainless steel, and are held in position between a lower locking collar and the base of the solvent reservoir. For optimum performance the length of each filter is at least five times the diameter (Hagdahl[3]), and each filter in a set is constructed so as to be twice the volume of the one beneath it. The distance pieces are all ¼ in. in length, and are pierced by a 1/32-in. hole. The filters vary in size from 79·2 mm. × 15·9 mm. to 23·8 mm. × 4·76 mm. internal dimensions, giving volumes of approximately 5,000 mm.³ and 125 mm.³. (These sizes are such that the necessary holes can be bored in a normally equipped workshop using standard British drills in 1/16-in. sizes.)

The overall length of each filter exceeds the internal by ¼ in. to allow for the insertion of a perforated disk to assist in the support of the adsorbent.

For carrier displacement adsorption chromatography[4], in which it is not necessary to make accurate and continuous observation of changes in refractive index of the eluate, a mixer as described by Hagdahl[1] is not required. In place of this a front straightener section terminating in a jet is placed at the bottom of the series of coupled filters for direct delivery into a fraction collector. After the individual filters have been filled under suction, they are introduced into the outer jacket starting with the jet, and adding distilled water after the addition of each subsequent section. The jackets are 1/16 in. shorter than the pile of filters and distance pieces, and when the upper end of the jacket is screwed into the base of the solvent reservoir, the filters are compressed into a completely fluid-tight column. Jackets of 14¾ in., 11 in. and 8 in. length enable columns of 9,875, 4,875 and 1,875 πmm.³ volume to be assembled, thus affording adequate variation in size of column for most purposes.

Columns of this type have proved of considerable use in the quantitative separation of mixtures of small amounts of aromatic acids. A description of this work will be published elsewhere. I wish to thank both Mr. L. Hagdahl and Prof. A. Tiselius for most helpful advice and encouragement.

Adsorption of Water and Methanol on Coal

In a recent issue of *Nature*[1], an address by Sir Charles Ellis was summarized. From the data and theories of various authors, an attempt was made to depict the structure of coal. While we are in general agreement with these ideas, we have information that makes one feature of the theory seem doubtful. The concept that coal is a porous system of high surface area is a major feature of the theory. This idea is largely derived from measurements of heats of wetting in methanol and from adsorption isotherms of methanol and water on coal[2]. Although measurement of heats of wetting is probably not a very accurate method of determining surface area, the surface areas obtained approximate to those obtained using adsorption isotherms of the vapours of the same liquid used in the heat of wetting measurement.

Results obtained in this laboratory (see table) indicate that the true surface area of coal is probably not measured by adsorption of methanol and water. These polar adsorbents are not physically adsorbed in the usual sense, and hence are not amenable to the usual Brunauer–Emmett–Teller treatment for derivation of surface area.

Coal	Surface areas* from isotherms of: Nitrogen −195° C. m.²/gm.	Water 25° C. m.²/gm.	Methanol 25° C. m.²/gm.
Lignite	3·5	290	307
High-volatile bituminous	1·5	94	115
Low-volatile bituminous	0·4	35	112
Sub-bituminous	1·6	310	408

* Computed from the simple Brunauer–Emmett–Teller equation, *J. Amer. Chem. Soc.*, **60**, 309 (1938), with the cross-sectional area of adsorbate molecules estimated in the usual manner.

It will be noted from the table that the surface areas measured by adsorption of nitrogen are quite small, scarcely more than could be accounted for by the external surface area. The surface areas measured by methanol and water are 50–200 times larger than the nitrogen Brunauer–Emmett–Teller areas and are in the range of values published by workers at the British Coal Utilization Research Association laboratories[2,3].

This type of behaviour is known for other materials. Studies of natural and synthetic polymers, particularly proteins and starch[4-6], have established that the adsorption of polar molecules does not give a measure of surface area but is probably related to the number of polar groups present in the adsorbent. However, the adsorption of argon or nitrogen gives surface areas of the same magnitude as those estimated from the average particle size[4,6,7]. These studies on synthetic and natural polymers suggest that water and other polar molecules actually penetrate the polymer and sorb on polar groups of the sorbent. Presumably, this phenomenon also occurs with coal. In addition, recent adsorption studies on carbon blacks indicate that the amount of adsorbed water[8-10], ammonia[8], or methanol[9,10] per unit area (as determined by nitrogen adsorption) increases as the oxygen content of the black per unit surface area.

These results will be published more fully elsewhere. In view of the information presented herein, we feel that a portion of the theory regarding the structure of coal should be modified.

Vegetative Propagation by Root Cuttings

Early in December 1949, we attempted the propagation by root cuttings of *Lagerstrœmia indica*, previously submitted for a fortnight to the action of low temperatures (0°–2° C.) or to a dry atmosphere (relative humidity, 50 per cent) for one or two weeks. Immediately after each of these treatments, the cuttings were put in a rooting medium of equal proportions of sand and garden soil, in a greenhouse, together with controls. All the cuttings were planted upright, as recommended by the Kaiser-Wilhelm Institut.

Two months later, the first examination of the cuttings was made, and it was found that the percentage of best rooting occurred with cuttings previously submitted to dehydration for one week. Cuttings treated by other methods were much more weakly rooted, possibly because of harmful effects of excessive duration of the treatment.

The control cuttings developed better than either those submitted to two weeks of dehydration or those subjected to the action of low temperatures, but not so well as those submitted to one week of dehydration. This seems to us natural, since the tests were made during the season favourable for this type of cutting.

One month afterwards, that is, three months after the experiment started, another inspection showed that the best rooting again belonged to the group of cuttings subjected to one week of dehydration (82 per cent), that the other two treatments had a poor percentage of rooting (8 per cent for cuttings subjected to two weeks of dehydration and 0 per cent for those subjected to low temperature) and that the controls rooted normally (42 per cent), as was expected, because the season was favourable for the propagation by this type of cutting. The advantage of the seven days dehydration treatment was again remarkable as regards average number of roots and their average length.

Encouraged by these results, we carried out new attempts late in March, a season not commonly used for the propagation of this type of cutting. Cuttings of *Pyrus communis* sub-sp. *boreana* were used, together with *Lagerstrœmia indica*, in these experiments. With the *Pyrus*, we found that, at the end of a month and a half, 70 per cent of those previously submitted to two weeks of dehydration had rooted, 48 per cent of those dehydrated for seven days, and no rooting at all of cuttings submitted to the low temperatures or of the controls. With the *Lagerstrœmia*, we obtained the following results. At the end of a month and a half, 38 per cent in the group subjected to one week of dehydration had rooted, 12 per cent of those dehydrated for two weeks, and no rooting at all of the cuttings submitted to the low temperatures and 2 per cent of the controls.

From these observations, we can draw the following conclusions:

(1) Better rooting of root cuttings of these plants is obtained, due to interception of the polar transportation of auxins[1] by means of dehydration.

(2) Seven days treatment gives the best results in the conditions under which these experiments were carried out.

(3) When polar transportation of auxins is intercepted, the rooting process becomes independent of the season in which the cuttings are planted.

These conclusions offer an explanation of the observation that the best results with root cuttings are generally obtained in the open air and not in greenhouses.

Northward Distribution of *Gammarus pulex* (L.)

Since the discovery that *Gammarus lacustris* Sars occurred in the fresh waters of the mainland of Scotland[1], and that the form previously identified as *G. pulex* was most probably this species, there seems to have arisen a tendency to assume that the former species replaces the more familiar *G. pulex* in that area.

However, mutual exclusion by no means occurs and the two species overlap to a marked extent. *G. lacustris* ranges from the north of Caithness and Sutherland southward to at least the Highland Line. *G. pulex*, on the other hand, ranges north through the *G. lacustris* area and has been found in Inverness-shire at Rothiemurchus in water of pH 6·2 at Drumintoul spring. The water of this spring has an alkalinity of 2·7, reckoned as parts calcium carbonate/10^5 (estimates made by the late A. C. Gardiner). This is a somewhat unexpected environment for *G. pulex*.

Farther north and close to Inverness itself, *G. pulex* has been taken from the water-supply source of Leys Castle, where the pH is 6·6. This water flows into a small ornamental lake the sides of which have been concreted and the vegetation of which suggests that the water is alkaline. This lake also contains *G. pulex* abundantly.

The species has been taken from a small stream at Poolewe in the west of Ross-shire. In this stream no *Gammarus* could be found in 1943, when specimens identified as *G. lacustris* were introduced from a neighbouring loch; but the specimens taken from the stream (and now recorded as abundant) and sent to me for examination in 1945 were *G. pulex*.

Thus, so far as I know at the moment, the most northerly limit of the range of *G. pulex* in Scotland is a little south of the border of Sutherland. However, work is at present being carried out on the eastern side of that county, which has not apparently been investigated.

It will be seen from the foregoing that the factors which limit the northward range of *G. pulex* are not at all obvious, and it would not surprise me to find that this species occurs, albeit sparsely, in both the northern counties.

In assessing the distribution of these amphipods, one has to take cognizance of the fact that populations are apt to fluctuate enormously and suddenly, so that conclusions drawn as to the absence of a species after the most careful search may, in a year or two, be reversed by the appearance of abundant specimens. Lochs Poll a' Chnoic and Sgeirach near Stoer, W. Sutherland, both lost their population of *G. lacustris* in this sudden and inexplicable manner; in the case of the former, a population of many year standing disappeared between April and August 1947.

New Forms of *Spartina townsendii* (Groves)

Within the past few years there has appeared i the Dovey Estuary a number of plants of *Spartin townsendii* differing markedly from the usual form and among these, two very distinct forms ar especially noticeable. One is very dwarf (3–4 in above ground) and with brownish leaves and sheath and flowering only sparsely. The other is variegate and has a leaf-blade with usually a yellow media portion and a band of green tissue along either side the flowering of this form is also sparse. As migh be expected, the dwarf-brown form does not occu in the fully-meadowed spartinetum. It is fairl widely distributed as small plants and as patches o up to 6–8 ft. in diameter in the more recently colonize and semi-open areas towards the upper end of th estuary, and among the *Spartina* which is invadin the grazed glycerietum.

The variegated form is restricted to a comparativel small area of 3–5 acres, and less than a dozen plant have been found, none being more than a few inche in diameter. It would appear, therefore, that thi form is either of more recent origin than the dwarf brown form or that it is incapable of persistence fo more than two or three years.

It is curious that so far the variegated form, whic is no smaller than a poorly grown specimen of th normal form, has not been found to occur elsewhe than within the limits of a patch of dwarf-brown although no connexion between them has been foun below ground. Consequently, its behaviour when fre from competition has yet to be studied. It is no intended to investigate this point and other aspect of the ecological relationship between these form while their cytology will be investigated by Pro P. T. Thomas.

The dwarf form has also been found by one of u in the Severn Estuary near Chepstow, and ther again only in the recently colonized zones. Althoug about twice the height of the dwarf form in the Dovey its relation to the normal form remains the same since on the mud of the Severn site even the norma form grows to about twice the height achieved o the sands of the Dovey.

While some degree of variatión has been recorde by other observers, particularly in regard to anthocya pigmentation, such marked variation as is recorde here does not appear to have been described els where, and the observations so far made suggest th possibility that these new forms represent the di integration of the formerly stable hybrid polyploi

Department of Botany,
University College of Wales,
Aberystwyth.
March 10.

FORTHCOMING EVENTS

Monday, July 23—Wednesday, July 25

Institute of Physics, Industrial Radiology Group (at 47 Belgrave Square, London, S.W.1).—Summer Meeting.

Tuesday, July 24—Friday, July 27

British Institution of Radio Engineers (at University College, Southampton).—Radio Conference, Sessions 3 and 4: Radio Communication and Broadcasting; Radio Aids to Navigation.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant (Grade B) **in Chemistry** at Constantine Technical College—The Director of Education, Education Offices, Woodlands Road, Middlesbrough (July 28).

Assistant (with a first-class honours degree in science or the equivalent) **to the Divisional Chief Scientist**—The Divisional Establishments Officer, National Coal Board, Northern (N. and C.) Division, First Floor, Ellison Buildings, Ellison Place, Newcastle-upon-Tyne (July 28).

Assistant Lecturers in Electrical Engineering—The Registrar, The University, Manchester 13 (July 28).

Head of the Engineering Department, Nigerian College of Arts, Science and Technology, Ibadan—The Secretary, Advisory Committee on Colonial Colleges of Arts, Science and Technology, 15 Victoria Street, London, S.W.1 (July 28).

Assistant in Mathematics—The Secretary, The University, Aberdeen (July 31).

Demonstrator in Zoology—The Dean of the Medical College, St. Bartholomew's Hospital, West Smithfield, London, E.C.1 (July 31).

Engineer I at a Ministry of Supply establishment in Lancashire, to be responsible for the organization and technical administration of the inspection of electrical and allied equipment ordered by the Atomic Energy Division—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting D.288/51A (July 31).

Experimental Officer (Botanist) and **Experimental Officers** (Zoologists or Chemists) for freshwater fisheries research at the Brown Trout Research Laboratory, Pitlochry, Perthshire—The Establishment Officer (Room 364), Scottish Home Department, St. Andrew's House, Edinburgh 1 (July 31).

Principal of the Melbourne Technical College—The Agent-General for Victoria, Victoria House, Melbourne Place, Strand, London, W.C.2 (July 31).

Scientific Officers in the Chief Scientist's Division, Ministry of Fuel and Power, London, for fundamental and applied research on problems affecting the production and utilization of fuel and power—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.466/51A (July 31).

Senior Scientific Officer or **Scientific Officer**, and **Scientific Officers** (Zoologists), for marine fisheries research at the Marine Laboratory, Aberdeen—The Establishment Officer (Room 364), Scottish Home Department, St. Andrew's House, Edinburgh 1 (July 31).

Demonstrator in the Department of Chemistry and Biochemistry—The Dean, St. Thomas's Hospital Medical School, London, S.E.1 (August 1).

Lecturer in Engineering Mathematics (including pure and applied mathematics and mathematical physics), and a **Lecturer in Medical Physics** (to act also as Assistant Physicist to Aberdeen Royal Infirmary)—The Secretary, The University, Aberdeen (August 1).

Chemists in the Materials and Analytical Section of a Ministry of Supply research and development establishment near London, (*a*) with experience of paints, varnishes and/or plastics, (*b*) with experience of paper and paper products and textiles—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.476/51A (August 4).

Mechanical Engineers and **Naval Architects** (Senior Experimental Officer grade) in Ministry of Supply headquarters, London—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting D.387/51A (August 4).

Principal Research Officer, Wildlife Survey Section of the Commonwealth Scientific and Industrial Research Organization, Canberra—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting No. 3464 (August 11).

Assistant Keeper (with a university degree in history or classics and a knowledge of either local history or general archæology) in the **Department of Archæology and Local History**—The Director, City Museum and Art Gallery, Birmingham 3 (August 13).

Lecturer or a **Senior Lecturer in Veterinary Hygiene**—The Registrar, The University, Leeds 2 (August 13).

Assistant Lecturer in Geography at Makerere College (University College of East Africa)—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (August 15).

Chair of Physics in University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (August 15).

Lecturer in Electrical Engineering—The Registrar, College of Aeronautics, Cranfield, Bletchley, Bucks, endorsed 'Lecturer in Electrical Engineering' (August 15).

Lecturer in Mechanical Engineering—The Principal, Wigan and District Mining and Technical College, Wigan (August 21).

Psychologists, Senior Psychologists, Principal Psychologists and **Senior Principal Psychologists**, in the Admiralty, War Office, Air Ministry and Prison Commission—The Secretary, Civil Service Commission, 6 Burlington Gardens, London, W.1, quoting No. 75/51 (August 23).

Electronic Engineers in the Ministry of Supply, to work near London or at provincial stations on the development and design of electrically operated systems for a variety of applications, including weapons, telecommunications and radar equipment—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting D.134/51A (August 24).

Lecturer in Veterinary Histology—The Registrar, The University, Liverpool (August 31).

Physicist, to work primarily on problems in agricultural meteorology—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (August 31).

Research Assistant (with a good honours degree in chemistry, with physics, and some knowledge of a biological subject) to work on physico-chemical aspects of biochemical and immunological problems—The Secretary, Lister Institute, Chelsea Bridge Road, London, S.W.1 (August 31).

Senior Lecturer in the Department of Physics, Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (September 1).

Chair of Mining—The Registrar, The University, Sheffield (October 6).

Assistant Director of the Botanical Gardens, Singapore—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting 27059/261.

Assistant Lecturer in the Department of Mathematics—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11.

Civil Engineers (with a degree in Civil Engineering and/or corporate membership of the I.C.E.) in the Chief Engineer's Department of the Rhodesia Railways—The London Agent, Rhodesia Railways, 11 Old Jewry, London, E.C.2.

Lecturer in Telecommunications—The Head of the Electrical Department, Polish University College, 4 Egerton Gardens, London, S.W.3.

Mechanical Engineer in the Public Works Department, Sudan—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Mechanical Engineer—4/8'.

Physicist (previous experience in the medical or biological application of ionizing radiations is desirable), and a **Junior Zoologist** (with an interest in experimental zoology and/or cytology)—The Director, Medical Research Council Radiobiological Research Unit, Atomic Energy Research Establishment, Harwell, Didcot, Berks.

Physicist, to undertake research work and theoretical studies into problems associated with the design and operation of nuclear reactors, an **Organic Chemist**, to take charge of a team engaged on organic chemical research, and an **Inorganic Chemist**, to carry out research work on chemical and radiochemical problems associated with atomic energy development, in the Research and Development Branch, Windscale Works, Sellafield, Cumberland—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, stating post applied for.

Physicists or Mathematical Physicists: (Ref. A.133/51A/BB) **Principal Scientific Officer** with experience of radar systems analysis and war-time operational research (a strong mathematical bias is desirable); (Ref. A.134/51A/BB) **Senior Scientific Officer** for theoretical investigations (a knowledge of statistical methods is desirable); **Aeronautical Engineer**: (Ref. C.217/51A/BB) **Senior Scientific Officer** with experience in planning and analysis of flight trials and application of results to project design (a knowledge of servo mechanism theory and practice is required); **Physicists, Mathematicians or Engineers**: (Ref. A.135/51A/BB) **Senior Scientific Officer** with research experience involving arithmetical applications of mathematics in the analysis of physical data, and the formulation of problems for solution by automatic computing machinery (a knowledge of aerodynamics an advantage); (Ref. A.136/51A/BB) **Senior Scientific Officer** with wide experience of methods of measurement in physics or engineering research, experience and up-to-date knowledge of electronics, at the Royal Aircraft Establishment, Farnborough—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting the appropriate Ref. No.

Principal Physicist to be responsible for the research work of a physics laboratory applying physical methods to the study of metals and to the development of methods of control of new metallurgical processes, and a **Physical Metallurgist** to be responsible for the research work of laboratories engaged on metallographic, crystallographic and physical metallurgical investigations—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, stating post applied for.

Research Assistant for isotope research (work will involve autoradiography, radioactive counting and maintenance of equipment, and animal experiments)—Mr. G. Rigby-Jones, Middlesex Hospital, London, W.1.

Research Assistant for microbiological assays of vitamin B_{12}, folic acid and L. citrovorum factor—The Registrar, King's College, Newcastle-upon-Tyne.

Research Manager (with a first- or second-class honours degree in physics, or equivalent) at the Research and Development Branch, Windscale Works, Sellafield, to take charge of a group of laboratories engaged on applied research work covering a wide field in general and nuclear physics and biology—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, quoting ARA/6.

Research Officer (with degree in physics, or equivalent) for work on problems in connexion with the use of fuel in domestic appliances, with particular reference to smoke elimination—The Assistant Secretary (Ref. A.23), British Coal Utilization Research Association, Randalls Road, Leatherhead, Surrey.

SENIOR EXPERIMENTAL, EXPERIMENTAL, and ASSISTANT EXPERIMENTAL OFFICERS, to undertake and assist with experimental work involving a wide range of chemical and physical atomic energy development problems, and a SENIOR EXPERIMENTAL OFFICER to design and assemble special electronic equipment for research groups working on atomic energy development problems, at the Research and Development Branch (Applied Research), Windscale Works, Sellafield—The Ministry of Supply, Division of Atomic Energy (Production), Risley, Warrington, Lancs, stating post applied for.

SENIOR IRRIGATION ENGINEER, and an ASSISTANT IRRIGATION ENGINEER, in the Public Works Department, North Borneo—The Director of Recruitment (Colonial Service), Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting No. 27322/68.

WATER AND DRAINAGE ENGINEER in the Public Works Department, Uganda—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting No. 27322/217.

EDUCATION AND INDUSTRIAL EFFICIENCY

In a paper on the strategy of industrial research, read before the Midlands Section of the Oil and Colour Chemists' Association last November (see *J. Oil Col. Chemists' Assoc.*, 34, 234; 1951), Mr. M. H. M. Arnold maintained that, in spite of the expansion of effort in industrial research in Great Britain during the past thirty years from very few up to tens of thousands of persons, of whom probably 5,000 are science graduates, with few exceptions British industry as a whole has shown little change in the past twenty or thirty years. He said that few firms could attribute their commercial success to their research departments, and that the position of the average research department, in authority, status and financial endowment, is low. He attributed this unsatisfactory position mainly to lack of an integrated approach to industrial problems. There is, he said, a false cleavage, largely traditional, between scientific, technical and economic aspects. He does not think that the size of a firm is often a decisive factor in success in research, except with very small firms; but he argued strongly for greater receptivity to new, and especially speculative, ideas, and also for greater care in general economic and technical appreciation before undertaking any expensive experimental work. In particular, he is sceptical about the value of research directed towards improving a craft process: in that field he believes that progress can only come by bulk production.

While the main thesis that industrial achievement in Great Britain compares poorly with our achievements in academic research is scarcely open to challenge, Mr. Arnold's analysis was not without critics during the ensuing discussion. If, however, he overstressed some of his points, his protest against waste of scientific man-power on work that is intrinsically unlikely to be profitable should be taken seriously. In essence, it strengthens the case argued elsewhere for strengthening the scientific and technical information services at the disposal of industry.

It would not appear from the examination of the three years experience of their working recently made by *Planning* (PEP Broadsheet No. 326) that the four development councils created under the Industrial Organization and Development Act of 1947 have contributed appreciably towards improving industrial efficiency, or linking industry more closely with the public it serves. Objections to such statutory bodies do not, indeed, appear to extend to statutory levies for research; but the inquiry made by PEP affords little evidence that either statutory or voluntary councils of this type are likely to make any real contribution to industrial development. The Cotton Board is an exception in that it is acknowledged, on the whole willingly, by the cotton industry and exerts a considerable persuasive influence there. However, PEP comments frankly that, even so far as the pooling of experience is concerned and the bringing of the least efficient firms up to the level of the more efficient, it is still uncertain that a development council is the best type of body for carrying out the changes that may be needed.

The decisive factor in industrial efficiency and in industrial research alike is that of leadership, of the supply of scientific workers, technologists and administrators of sound judgment, wide outlook and understanding, capable of selecting the right targets and organizing efficiently. As the Percy Report observed in 1945, the failure to secure the fullest possible application of science to industry is in part a failure in education; this point was stressed independently recently, first by Mr. F. Scholefield, president of the Society of Dyers and Colourists at the Society's annual dinner, and by Sir John Maud in his paper to the Royal Society of Arts on "A Century of British Education". Sir John regards the situation, indeed, as a major problem of British education: however much room there may be for reasonable men to differ about the best means of achieving our goal, the provision for technological education in both university and technical college which we in Britain have inherited must be vastly improved if we are to avoid just and bitter censure from coming generations of our countrymen.

Sir John Maud recognizes that both the universities and the technical colleges have much to contribute: the best universities have their tradition as the common home of science and the arts, research and teaching, of recluses and men of the world, their tradition of independence and inflexible attachment to the highest standards of scholarship; the best technical colleges have an inheritance of intimate association with industry. He said he is confident that we shall find ways both of conserving the peculiar virtues of our various institutions for higher technological education, and, at the same time, of learning from the different experience of the United States, Switzerland, Germany and other countries. Dr. C. J. T. Cronshaw, at the Society of Dyers and Colourists' annual dinner, spoke no less confidently on this point; but he also insisted that a first-class technologist must be also a first-class scientist: arbitrary division between science and technology, he said, is unwise, and he thinks the only method of training technologists is to train scientific men and give them, within the industry itself, the opportunity to become technologists.

Mr. Scholefield, while accepting as justified Dr. Cronshaw's emphasis on the importance of science, inclined to support the view that alternative methods of training technologists are also possible. The divergence between the two views would doubtless be clarified if the meanings of the terms used by the speakers were defined precisely, and particularly exactly what is meant by 'technology'. There are obvious limits to the extent to which technology in the sense of day-to-day practice can be learnt anywhere except in the industry itself, and Dr. Cronshaw's insistence on the importance of science is in keeping with all that was said at the Home Universities Conference last December as to the qualities for which industry looks first in its recruits from the universities, and the desire for graduates of mature education as distinct from merely high technical ability.

An important part of a liberal education is the knowledge that it conveys to the student, often through the literature and history, of the traditions ideas and beliefs that prevail in his society. It helps too, in the formation of sound judgment and in giving due weight to the human qualities to which Dr. D. W. Hill directed particular attention in a paper on the chemist as administrator last Octobe (*J. Roy. Inst. Chem.*, 74, 447; 1950). Such knowledge and judgment cannot be acquired in the range o technological studies, and in this sense science and technology do not provide a liberal education, as Lord Cherwell and others contend. Even Sir Graham Savage, in an address on the future development of higher technological education to the Union of Educational Institutions on June 8, supported this dubious proposition; though he urged, too, that industry can only be efficient if it is manned and directed by a staff in which highly trained and efficient technologists are fully represented.

Sir Graham appeared to be thinking primarily o the receptivity of industry to new scientific and technical ideas; but how essential such humane knowledge and judgment are to anyone who aspires to play a leading part, even as technologist, in the world to-day, can scarcely be better demonstrated than in the study of the composition of the boards of nationalized industries which the Acton Society Trust has just issued under the title "The Men on the Boards"*. This pamphlet disposes effectively of the wilder charges against members of the boards, and indeed gives a firm rebuke to those who make unfounded charges; but it indicates that, by and large, failure has occurred just at this point.

Members of national boards have been chosen simply for their ability and experience in industrial and administrative affairs, and it is manifest that business ability is not enough. Ignoring factors peculiar to single boards, the general review leads to the conclusion that national boards have not succeeded to any marked extent in dispelling the traditional suspicions of employees and in opening up an era of harmonious co-operation. Sometimes they have failed to raise important topics for consultation until after decisions have been made; and again, requests from the employee side to discuss certain matters have been rejected out of hand Some boards have taken a narrow view of their responsibilities in such matters as the provision of training and research, and have been reluctant to experiment in this field. Training programmes have frequently been limited in scope and have ignored the need for giving the employee a wider knowledge of the structure of his industry and his responsibilities as a citizen in that context.

Again, there is evidence that the boards have failed to appreciate the unique character of the task of running an entire industry on a monopolistic basis, and of the need for working out fresh solutions for the completely new set of organizational problems which arise. They have not always shown the imaginative approach and willingness to experiment with new atterns of organization and communication for which the situation calls. In general, they have also een reluctant to explain themselves to the public.

---

* The Men on the Boards: a Study of the Composition of the Boards of Nationalised Industry. (Nationalised Industry Series, 4.) Pp. iii+22 (Claygate: Acton Society Trust, 1951.) 2s.

For such reasons the Acton Society Trust suggests hat what is required is a trustee board composed f people of many types of ability, and selected articularly for their imagination, adaptability and readth of vision. They must be competent to take he review of wide issues which is an essential part f their duties. Equally, the organization must rovide for more effective contact with employees.

In this study there are no illusions as to the diffiulty of obtaining a sufficient range of experience for he task; and the suggestion is advanced that a small permanent commission, with a qualified staff, should be constituted for appointing members to the public boards. But one of the important features of this tudy is the implication it has for other fields. Part of the responsibility for the failure of the national boards lies clearly on the inability of the trade unions hemselves to provide men from their membership of the necessary vision and judgment. The very growth in power of the trade unions makes the question of wise leadership for them a national and not a sectional issue; yet at the same time the series of sporadic unofficial strikes have emphasized the inherent weakness of their present organization.

It is in such a context as this that the question not merely of higher technological education but also of higher education generally, whether full-time or extra-mural, needs to be considered. It is not a question of selecting and training men or women specifically for leadership. It is rather one of providing the education which will ensure that those called to positions of responsibility in any walk of life are so equipped that they can bring to their task, not merely technical or scientific knowledge and practical experience, but also wide vision and the understanding of the human issues which will prevent sectional from prevailing over national interests. Only men and women so equipped are capable of the clear and balanced thinking which is required both in handling the problems of organization and policy in undertakings of the scale of nationalized industry, and in the selection of the right targets for research and development.

AUSTRALIAN GEOLOGY: A REGIONAL SYNTHESIS

The Geology of the Commonwealth of Australia
By the late Sir T. W. Edgeworth David. Edited and much supplemented by Dr. W. R. Browne. Vol. 1. Pp. xx+747+58 plates. Vol. 2. Pp. iv+618+plates 59–84. Vol. 3. 5 maps. (London: Edward Arnold and Co., 1950.) 3 vols., £12 12*s*. 0*d*. net.

THESE volumes, unequalled among regional surveys of comparable dimension for their scope and range of completeness, mark a major event in the annals of Australian geology and form a fitting monument to the memory of Sir Edgeworth David, their chief architect. For this stupendous undertaking, begun a quarter of a century ago and now at last brought to completion, no one was so fitted as Sir Edgeworth David himself. His own personal researches had covered an amazingly wide field embracing geological problems in every State of the Commonwealth, and he had, through half a century, made himself familiar by extended travel with the field-work of his colleagues in every corner of the continent of Australia.

As the first product of Sir Edgeworth David's labours a large coloured geological map of the Commonwealth on a scale of 1 : 2,990,000, together with a slender volume of explanatory notes, had been issued in 1932. The book itself, however, remained unfinished at the time of his death in 1934 and the task of completing it fell to his colleague, Dr. W. R. Browne. The long delay in its appearance has been due in part to the Second World War, when publication proved impossible, and to the further revision which was deemed advisable at its close, to bring the manuscript so far as possible abreast of the more recent advances. This revision has, in fact, involved rewriting part of the original text, and geologists owe Dr. Browne a debt of gratitude for his unselfish devotion to a labour which must have been beset by many difficulties.

The book is in three volumes: the first, of 747 pages, deals with historical geology, including a chapter on the geology of Australian New Guinea, while the second (618 pp.) treats of the physiography and economic geology. The third volume contains the coloured geological map issued in 1932 together with a map of Australian New Guinea (1 : 2,500,000) which, though previously published by the Directorate of Army Research, had not become generally available.

The pattern of treatment in the section on historical geology is the description of the formations by States, each chapter presenting a geological distribution map of the period and concluding with an extensive bibliography.

The final chapter of the first volume attempts a review of the tectonic history of the continent of Australia, considering its relations with Asia, the framework within or about which it was built and the events leading up to its present isolation.

The main impression given by these volumes is one of great completeness, of a story which has not only summarized the whole wealth of published data but has also essayed to provide the vitalizing threads of synthesis. Occupying as they do not less than one-sixth of the area of the continent and forming the repositories of leading ore deposits, Pre-Cambrian formations come to play a major part in Australian geology. Their description covers a hundred pages of the first volume, and the geology of their economic products is lucidly discussed in many chapters of Volume 2.

The correlation of the various divisions of this vast Pre-Cambrian terrain is beset with intricate problems and, as might be expected, stratigraphic and structural knowledge of the more complex areas is best known from centres of active mining. It is clear from these accounts that in Australia, as elsewhere, an immense field of research on the older rocks lies open to the investigator.

An admirable description is given of the widespread Upper Pre-Cambrian series, which holds a major glacial horizon and appears to pass in many places conformably into fossiliferous Cambrian, thus suggesting that parts of the series are Lipalian in the sense of Walcott, bridging the time between the Pre-Cambrian and the Palæozoic.

During much of Palæozoic time and later, the Australian continent is pictured as bounded east and west by geosynclines.

In particular, the attention of the reader is arrested by the account of the great tectonic depression known (and so named by Schuchert) as the Tasman geosyncline, covering at various times much of eastern Australia and Tasmania. The synthesis of events that gave growth and change to this majestic structure forms a central theme in the discussions of the Palæozoic System, and the detailed account of its structure, its repeated orogenies and synchronous or subsequent granitic epochs form one of the most fascinating sections of the book.

The magnificent vista thus skilfully revealed will give added stimulus to the prosecution of major groups of researches, providing, for decades to come, lines of investigation for workers in all departments of the science.

In the long geological history of Australia so clearly depicted, it is pleasing to find that measured emphasis is given to the place of vulcanism and plutonic igneous activity, with an attempted assessment of their role in the stratigraphic and tectonic record. Knowledge of the vulcanicity is perhaps most detailed among the Tertiary lava floods of eastern Australia, where petrological investigation has been more intensively carried forward. The book is enriched by an up-to-date chapter on Australian New Guinea prepared by officers of the Australasian Petroleum Co. One of the more interesting disclosures emerging from recent study of this region, and here recounted, is the refutation of the long current interpretation of the occurrence of over-thrusts of Alpine type among the younger folded rocks; on the contrary, the mountain-building movements are now recognized as being primarily vertical rather than horizontal.

The section on physiography, a work of 141 pages in the second volume, provides an exemplary account of the main features of the geomorphology of the continent of Australia. The larger section of the volume, however, is devoted to economic geology, commencing with a general account of the distribution of ores in space and time and their close relation to the epochs of plutonic intrusion.

Thereafter each of the chief metals is described in chapters divided by States. Important sections deal with coal, lignite and oil shale, and the descriptions conclude with a survey of artesian basins which cover in the aggregate upwards of one-third of the area of Australia, the largest in regions of low rainfall. The results of the prolonged study of these basins, the problems of their stratigraphy, structure and chief aquifers, and of the flow and salinity of their waters, are very completely set out with copious reference to the extensive researches devoted to this field. Many other fascinating topics, which in the limits of a short review it is impossible adequately to consider, are lucidly expounded in this monumental treatise.

Here will be found the discussion of such diverse subjects as the evidence for no less than five ancient glaciations, three of them of major extent and duration; the nature of the correspondence between recorded diastrophisms and those of extra-Australian regions; the rise and extinction of the distinctive land flora of the Carboniferous and the controversial problem of the Permian boundary; the status of the Papuan geosyncline; the disruption of the Australasian continent; and the antiquity of man.

The topics are legion, and it would appear that n significant study devoted to the regional geology ha escaped summary. The book without doubt wi endure as the chief reference work on Australia geology for many years. In the concluding sentenc of the introduction the study is described—and wel described—as at once a stocktaking and an interpretation. That it also forms a secure foundation o which the student of to-morrow may build Dr Browne may be emphatically assured, and ca proudly so claim. The impressive work marks, indeed a vantage point in the history of advance in regiona geology with which the names of David and Brown will always be associated.

C. E. TILLEY

THE TEACHING OF COLLOID CHEMISTRY

Kurzes Lehrbuch der Kolloidchemie

Von Dr. B. Jirgensons und Dr. M. Straumanis. Pp. viii+282. (Berlin, Gottingen und Heidelberg Springer-Verlag, 1949.) 21.60 D. marks.

THE importance of a sound knowledge of colloid science to the chemical technologist has resulted in more attention being paid to this subject in university courses in recent years. A number of excellent monographs and larger volumes aimed mainly at the already trained worker exist, but there are few treatments written frankly for the student This compact work by Drs. B. Jirgensons and M Straumanis is therefore welcome. It is unpretentious it is a university text-book and nothing more, but it is a good one. The authors have known what to leave out as well as what to put in. The student is guided logically through what can be pedagogically an awkward subject, and the introduction to modern physical techniques comes early. This is a good point, as it is unwise to overload the new student with all the classical burden; it is better to present him early on with a sound framework into which he can fit further facts and observations as he comes across them.

The descriptions of experimental techniques are of just the right standard: the main features and underlying theory are given, and the reader is guided to the essential literature. In a second edition, the opportunity might be taken to include a short section on the low-angle X-ray scattering method for particle-size determination in the 100-A. range. At the same time, the section on the X-ray line-broadening method could be slightly amplified to cover the intensive discussions on this subject which occurred in Great Britain during the war years.

As might be expected, the book to some extent reflects the barrier of the war period. This could easily be remedied in a new edition which, while broadened to embrace recent American and British advances, should not lose the present book's high quality of presentation. In my opinion, this short book of some 280 pages would be well worth translating into English for the benefit of the many students who find difficulty in reading German. It does not compete with recent larger works which can give a much fuller and more thorough treatment than is attempted by Jirgensons and Straumanis. Its attractive features are its succinctness, its wise selection of material and the exceptional clarity of treatment.

D. P. RILEY

SCIENCE AND TECHNOLOGY OF POWDER METALLURGY

Treatise on Powder Metallurgy

By Dr. Claus G. Goetzel. Vol. 1: Technology of Metal Powders and their Products. Pp. xxvii+778. 10s. Vol. 2: Applied and Physical Powder Metallurgy. Pp. xviii+910. 144s. (New York and London: Interscience Publishers, Inc., 1949–50.)

COMPARATIVELY little is generally known of the increasingly important part played by the products of powder metallurgy in industry. Possibly the publication of this encyclopædic treatise on the subject may conduce to a wider knowledge of the subject, especially in engineering circles. Powder metallurgy is defined as the art of producing metal powders and objects shaped from individual, mixed or alloyed metal powders, with or without the inclusion of non-metallic constituents, by pressing or moulding objects which may be simultaneously or afterwards heated to produce a coherent mass, either without fusion or with fusion of a low-melting constituent only.

The earliest products on a commercial scale were porous oil-impregnated bearings of bronze. To-day the most important materials produced are cemented carbide tools which in a few years have revolutionized the operations of cutting, grinding, machining and milling, and have accelerated production and effected economies beyond any expectation of engineer or manufacturer; at the same time the products of powder metallurgy have suggested solutions to many outstanding problems in the production of high-temperature resistant materials, to mention only one group of potentialities.

The Second World War enormously accelerated progress in every department of powder metallurgy, and workers therein have felt the lack of any comprehensive survey which would correlate theory and practice and at the same time attempt an over-all picture of the development and progress which have been so notable a feature of the past decade. The two volumes by Dr. C. G. Goetzel most admirably fill that void. Vol. 1 covers the technology of the processes of the art, discusses the underlying principles and provides a historical review. Methods of powder production and the characteristics and properties of powders are discussed in detail. Methods of testing powders are described, and attention is given to the widest range of commercial powders. The behaviour of powders under pressure and the moulding of powders into solid form are dealt with, followed by a discussion of dies, punches, presses, and, after consideration of hot pressing, the principles of sintering and its practice, including furnaces and atmospheres as well as finishing treatments. Vol. 2, divided into two parts, deals first with applied powder metallurgy and supplies the fullest account extant of the happenings and progress of the past ten years. The sections cover refractory metals and alloys, hard metals and compositions, electrical and magnetic materials, ferrous and non-ferrous materials for structural parts, porous products, friction materials and dental alloys. The second half of the volume, on physical powder metallurgy, describes and discusses the important phases of the physical metallurgy of metal powders, comparing the physical properties of sintered and fused industrial alloys and metals. An excellent survey is given of sintered metals and alloys for potential industrial use; the stress analysis of sintered metal structure and an appraisal of testing methods provide material of outstanding practical value, while there is a full and most useful review of theories of bonding and sintering.

A section is devoted to the future of powder metallurgy, and it is perhaps the future that should be stressed, for no other technique has such potentialities or holds out such promise as powder metallurgy. Not only does it overcome the handicaps that are inherent in the limitations imposed by the necessity for melting and then cooling-down molten metal, but also it overcomes the incompatibilities arising from widely divergent melting points, large variations in electrical or heat conductivity, and the differences between metallic and non-metallic bodies. It can produce unique materials, and these two volumes by Dr. Goetzel provide a guide and a commentary comparable with the best that is available in any other subject. Moreover, the documentation is of a high order and is to be supplemented by a third volume which will comprise a classified and annoted bibliography covering both literature and patents.

H. W. GREENWOOD

OPERATIONAL CALCULUS

Operational Calculus based on the Two-Sided Laplace Integral

By Dr. Balth van der Pol and Dr. H. Bremmer. Pp. xiii+415. (Cambridge: At the University Press, 1950.) 55s. net.

ALTHOUGH operational calculus is not derived from anything fundamentally new in mathematics, it is nevertheless a comparatively modern technique. Since its recognition as a valuable weapon, both in pure mathematics and mathematical physics, much literature has appeared, ranging in scope and manner of presentation from the practical text-book to the erudite treatise. In almost all cases where the analytical background has been worked out in detail, the author has adopted one of two main courses: either following Heaviside in using an operator $1/p$ defined as a definite integral; or by using the so-called Laplace transform $\int_0^\infty \exp(-pt)f(t)dt$, or in some instances $p\int_0^\infty \exp(-pt)f(t)dt$. It is not intended here to compare the advantages and disadvantages of these alternatives (which are, of course, mathematically equivalent), but to discuss briefly a third method of attack based on the replacement of the one-sided integral, quoted above, by a two-sided one of similar character, namely, $p\int_{-\infty}^\infty \exp(-pt)f(t)dt$.

It is at once clear that this modification of the Laplace transform does not basically affect the ideas and methods of procedure encountered in the one-sided case. We still have, for example, a unique 'image' $\varphi(p)$ derived from the 'original' $f(t)$ by the integral transformation, and a complex inversion-integral enabling us, in certain cases, to determine explicitly the original of a given image. Furthermore, we are still in possession of the fundamental asset of the operational calculus in that we can study the properties of many apparently quite intractable and often discontinuous functions of a real variable t by means of their smooth, analytic (and therefore much simplified) images in the p-plane. What, therefore, are the advantages of the two-sided transform, and what are its corresponding disadvantages, if any?

Three advantages are summarized by the authors, in their preface, as follows: the class of functions $f(t)$ suited to operational treatment becomes much larger; the transformation 'rules' are considerably simplified; and the entire treatment becomes more rigorous. On the other hand, the disadvantages are mainly of a theoretical kind, being for the most part concerned with the precise stipulation of the strip of convergence $\alpha < \mathbf{R}(p) < \beta$ for which a particular relationship is valid, and are therefore often of little interest or importance to the more practical student. It would seem to be well worth while to illustrate the above remarks by means of actual examples, where possible. Using the symbol $\sim$ for the equivalence of $f(t)$ and $\varphi(p)$, it can easily be shown that $\exp(-\alpha|t|) \sim 2\alpha p/(\alpha^2-p^2)$, while in the one-sided theory there is no proper image. Again, $\exp(-\alpha t^2)$ $(\alpha > 0)$ $\sim \sqrt{(\pi/\alpha)}p \exp(p^2/4\alpha)$ for all p, a much more compact result than the one-sided image $1/2 \sqrt{(\pi/\alpha)}p \exp(p^2/4\alpha) \operatorname{erfc}(p/2\sqrt{\alpha})$. Yet another example of a much simplified image is afforded by $1/(1+e^t) \sim -\pi p/\sin \pi p$ instead of one involving logarithmic derivatives of the gamma function. As regards the simplification of the transformation 'rules', one may quote an extremely elegant form of the 'shift' theorem, namely, $f(t+\lambda) \sim \exp(\lambda p)\varphi(p)$ for all real λ, while Borel's 'composition' theorem becomes

$$\frac{1}{p}\,\varphi_1(p)\varphi_2(p) \sim \int_{-\infty}^{\infty} f_1(u)f_2(t-u)du,$$

a valuable improvement on the old form on account of the constant upper limit of integration. There is, admittedly, a compensating difficulty here, in that a common strip of convergence is sometimes not available, but this is easily obviated by use of the 'shift' theorem in the majority of cases. It would be outside the scope of a review to attempt to deal seriously with illustrations of the authors' third contention that the entire treatment becomes more rigorous, and so it must suffice to say that there are numerous places in the text where such illustrations are presented.

The book is divided into sixteen chapters, covering an unusually wide range of 'operational activity', beginning with an introduction by way of the Fourier transform, followed at once by a detailed survey of the elementary 'images' and rules. Special attention is then focused on the Heaviside 'unit' function and its derivative, Dirac's δ or 'impulse' function, both of which play an important part in the two-sided theory. After further chapters concerned with theoretical development, the authors deal very thoroughly with linear differential equations (including those with variable coefficients) and their many applications to electrical circuits, networks and filters.

Many special functions, in particular those of Bessel and Legendre, and the polynomials of Hermite and Laguerre, are then discussed, and there are also chapters dealing with difference equations and integral equations. Finally, we have partial differential equations, both in one variable and severa variables, with the introduction of a *simultaneou* operational calculus enabling the reader to study a new treatment of Green's functions, potential theory and Maxwell's electromagnetic equations.

Appendixes are supplied containing a summary o the general rules (aptly described by the authors as the 'grammar') and a classified 'dictionary' of the images of the more familiar functions, all of which is absolutely indispensable to anyone intending to make a systematic use of the operational calculus, either in mathematics or physics.

By way of criticism, it must be pointed out that as the work is a translation from a series of lectures in Dutch, the language is from time to time somewhat clumsy and stilted, and there are even instances in which a wrong word has been used. Such imperfections, however, are of little consequence in a book of this kind, where a large part of the text is purely symbolic. The excellent reproduction has regrettably resulted in a price that may well be outside the range of many an impoverished student, but those whose purse can still rise to the occasion will be amply rewarded by the possession of a copy.

J. H. PEARCE

ANIMAL PSYCHOLOGY

Handbook of Psychological Research on the Rat

An Introduction to Animal Psychology. By Norman L. Munn. Pp. xxvi+598. (Boston and New York: Houghton Mifflin Co.; London: George G. Harrap and Co., Ltd., 1950.) 35s. net.

A FEW years ago, Dr. N. L. Munn produced a book called "Psychology: The Fundamentals of Human Adjustment". It immediately won its way to high popularity in many universities in the United States and in Great Britain. It is a good general introduction to psychology.

The author's success is likely to be repeated with this new work, particularly if those who recommend it direct attention to its sub-title, which does not appear on the spine or the front cover of the book It is, indeed, a handbook of psychological research on the rat, with a bibliography of 2,500 references, but it is much more than that: it is a fine, scholarly record of numerous investigations that display clearly the foundations of the psychologist's claims to be a man of science and to be able to make a contribution to science that other scientific workers cannot make. The non-psychologist who seeks a straightforward illustration of this point will find it in the section (pp. 272–278) that deals with studies of 'delayed reaction'.

Although most of the book is taken up with work on sensory and learning processes, about a quarter of it is devoted to 'abnormal and social behaviour'. This is a welcome sign that rat psychologists are throwing off the tendency to narrow-mindedness that for many years has restricted the scope of their investigations and has incidentally deprived many non-laboratory psychologists of the advantages of close contact with them. One notable recent development in this field has been experimentation on the effects of electroconvulsive shock. As Dr. Munn remarks (p. 441): "Although the first study of electroconvulsive shock on rats was published in the present decade, the literature is already extensive and new studies are pouring in". Among the investigators who have become prominent in this area is Dr. Roger W. Russell, formerly of Pittsburgh, who has recently succeeded Sir Cyril Burt as professor of psychology in University College, London.

The summary and conclusions on abnormal behaviour (p. 463) and social behaviour (p. 473) will appeal very much to a wide range of readers, though they tend to give the gloomy impression that rats are on the whole no more regardful of other rats than are human beings of each other. Thus (p. 475): "The clearest instances of what might be regarded as truly cooperative behaviour are those in which two rats learned to take turns in sitting on a platform so that each could feed without receiving an electric shock".

Dr. Munn's italicized postscript (p. 476) gives an excellent indication of the content of his book. "We have seen that the rat is an exceedingly useful tool for the investigation of a wide range of problems having relevance for human psychology. Of especial significance from this standpoint are the findings on: (1) physiological aspects of motivation, (2) contributions of sensory processes in learning, (3) the role of brain processes in learning, retention, and reasoning, (4) effects of drugs and vitamins on the learning process, (5) equivalence of stimuli in perceptual response, (6) evaluation of learning theory, (7) effects of nutritional conditions upon abnormal behaviour, (8) conflict as an etiological factor in behaviour disorders, (9) analysis of the procedures and outcomes of shock therapy and (10) objectification of psychoanalytic mechanisms. In some of these fields the research is well advanced and rather definite conclusions are possible. . . . In others, and particularly the last-mentioned, research is in its initial stages."

Alec Rodger

BIRDS OF PARADISE AND BOWER BIRDS

Birds of Paradise and Bower Birds

By Tom Iredale. Pp. xii+239+33 plates. (Melbourne: Georgian House Pty., Ltd.; London: Phoenix House, Ltd., 1950.) 105s. net.

On p. 2 of this book there occurs the following pronouncement: "The acme of uselessness in ornamentation appears to have been reached in the Birds of Paradise, as here coloration and feather structure appear in the male, making it a very beautiful creature, while the female has remained very ordinary". It is a minor tragedy that the book, superbly illustrated by Mrs. Iredale (Lilian Medland) and finely produced by its Melbourne publishers, is in its text a hotchpotch of such statements, old-style taxonomy and long and uncritical quotations from the frequently inaccurate accounts of collectors and bird photographers.

The birds of paradise are unrivalled in their epigamic adornments and astonishing in the use they make of them. The bower birds are generally not only of outstanding physical beauty, but also perform complex displays at their bowers and display-grounds to which they bring coloured or shining flowers, berries, leaves, shells and bones. Each species makes its choice according to the hereditary conservatism of its kind. Three species paint the walls of their bowers with various substances. One Australian bower bird actually fashions a tool to help it apply the paint which, in this instance, is a mixture of saliva and charcoal obtained from logs burnt by bush-fires. Another clears a patch of dark jungle floor and covers it with a striking pattern of leaves sawn from neighbouring plants with a remarkable 'toothed' beak that is adapted to the job. Yet in this book no attempt has been made to relate habit and function. Mr. Iredale has steadfastly ignored all the implications of the work of Howard, J. S. Huxley, F. H. A. Marshall, Lorenz and other pioneers who have revolutionized our understanding of the function and physiology of display during the last three decades. Mr. Iredale has likewise largely ignored the opinions of Stresemann, Stonor, Mayr and others who have done so much work on the anatomy and phylogeny of the birds of paradise. He dismisses a little contemptuously the possibility that some of the rare birds, collected and described during the trading days, are the result of natural hybridization. The present reviewer has never been directly concerned with this problem; but he cannot help feeling that it is the careful studies of Meise and Stresemann, rather than the present generalizations, that carry the more weight with the disinterested worker in a neighbouring field.

On the credit side, in addition to the coloured illustrations, typography and binding, there are interesting historical data concerning the legendary attributes of the birds of paradise. Thus, John Huyghen van Linschoten, after a voyage to the East Indies: "In these Ilands onlie is found the bird, which the Portingales call passaros de Sol, that is Fowle of the Sunne, the Italians call it Manu codiatas, and the Latinists, Paradiseas, and by us called Paradice-birdes, for ye beauty of their feathers which passe al other birds; these birds are never seene alive, but being dead they fall on the Ilands: they flie, as is said alwaies into the Sunne, and keepe themselves continually in the ayre, without lighting on the earth, for they have neither feet nor wings, but onlie head and body, and the most part tayle . . .". This legend arose, of course, from the birds' unearthly beauty and because trade-skins (which were bartered from tribe to tribe long before recorded Pacific history) often lacked legs and wings.

Other accounts stated that besides lacking wings and legs, paradise birds also lacked stomachs. But a latter-day sceptic had the following to offer: "It was believed by the credulous and ignorant, the most numerous class of men, that it lived alone upon the air and dew; that it had no intrails, nor feet; but remained perpetually floating upon the air while sleeping, as well as while awake; while hatching and laying as well as while procreating its young. . . . Instead of a stomach and intestines, which, to so extraordinary a feeder, would have been useless, the cavity of its abdomen was said to be filled with fat."

There is also included brief but welcome information concerning the great nineteenth-century travellers A. R. Wallace, D'Albertis, Beccari and Macgregor. But, incredibly, the book has no references and there is no index.

Whatever one's friendship and affection for the author—extending over twenty years—one cannot find in the text much else to praise. It is "as dry as the remainder biscuit after a voyage". Mr. Iredale has indeed strange places crammed with observation—and he has vented it in mangled form.

A. J. Marshall

Electromagnetic Theory

By Oliver Heaviside. Complete and unabridged edition of Vol. 1, Vol. 2, and Vol. 3, with a Critical and Historical Introduction by Ernst Weber. Pp. xxx+386. (New York: Dover Publications, Inc.; London: E. and F. N. Spon, Ltd., 1950.) 63s.

ADMIRERS of Oliver Heaviside's work will be highly appreciative of the appearance of an unabridged edition in a single volume of his three volumes on "Electromagnetic Theory". In spite of the excellent English in which it is written, Heaviside's work is in general by no means easy to read, and only by patient search and serious study can real benefit be derived from much of it. A major difficulty in the earlier editions was the absence of a detailed index to supplement the tables of contents, and there can be no doubt that this lack accounts for the fact that a number of his important contributions were overlooked for many years. It is unfortunate that this omission has not been repaired in the new edition.

The book is a most attractive reproduction of the original text and is preceded by a historical survey by Ernst Weber, director of the Microwave Research Institute of the Polytechnic Institute of Brooklyn. This introduction comprises a short biography of Heaviside and appreciations of his contributions to vector analysis, electromagnetic field theory, transmission line theory, operational mathematics, loaded communication lines and electromagnetic units, each followed by a list of books and other texts dealing with developments of the respective topics. This survey is well written but is too short to do full justice to the subsequent text, and readers will find it helpful to refer to the much extended appreciation of Heaviside's work contained in the recently published Heaviside Centenary issue of the *Journal of the Institution of Electrical Engineers*, and be able thereby to correct a number of excusable errors in Dr. Weber's biographical statement. The thorough review of Heaviside's work given in this centenary issue makes it unnecessary to comment further on the subject-matter of the book.

WILLIS JACKSON

Measurements of Mind and Matter

By Dr. G. W. Scott Blair. Pp. 116. (London: Dennis Dobson, Ltd., 1950.) 9s. 6d. net.

THE rheologist's concern is with things like the 'body' of a dough or the 'firmness' of a clay, qualities which defy reduction to simpler physical concepts and which are assessed more consistently by human judgment than by conventional measuring-technique. Materials of this kind can be classified in terms of 'quasi-properties', intermediate between, say, viscosity and elasticity, which appear dimensionally awkward. These represent the response of a material to a changing situation as a whole rather than to a simple change of one or two factors, and Dr. G. W. Scott Blair likens this kind of classification to the methods of Gestalt psychology. He discusses the meaning of measurement in general from the philosophical point of view, and shows the dimensional difficulties that can arise in practice.

The real argument of the book is that in the relatively unexplored field of 'psychophysics', which constitutes the frontier between physics and psychology, a different approach from that of pure physics may be justified; this in itself needs no elaboration, for anything amenable to a purely physical treatment is surely well within the frontier. Nevertheless, a number of controversial points are raised, and th author's own reflexions on them are given in detached and critical manner. The book is addresse to the non-specialist and the general reader, th latter of whom may find it rather a tough proposition and its object is rather to give a wider currency t the fact that certain problems exist than to lay dow solutions to them.

Warne's Metric Conversion Tables

Designed by Otto Klein. Computed by Scientifi Computing Service, Ltd. Pp. 104. (London an New York: Frederick Warne and Co., Ltd., 1950. 15s. net.

THESE conversion tables have been compiled t meet the demand for a quick and efficien system of converting Imperial and American measure into the metric system, and vice versa. The British and American measures are in the main identical; but confusion is sometimes caused with the Imperial and American gallons, and with the American short and the British long tons. This book certainly covers fairly thoroughly the relations between these, as well as the conversion into metric units. Measures of weight, length, speed, surface, volume and capacity are included, as well as reduction tables, conversion of one temperature scale to another and pressure tables; altogether there are eighty tables.

As regards the use of this book, it will, of course, have a limited appeal in schools and universities, since the conversions are given to a higher degree of accuracy than is ordinarily required (though it might be of some use in schools if it did nothing more than resuscitate the long-forgotten art of 'learning tables'). But its chief use is in the wider field of commerce, and it should be of great value to those engaged in business transactions between countries which have adopted the Imperial measures and those using the metric system.

Natural History

Birds and Mammals. By David Seth-Smith. (Reason Why Series.) Pp. 198. (London: Herbert Jenkins, Ltd., 1949.) 7s. 6d. net.

DURING his long experience as curator of mammals and birds in the London Zoo and as that popular broadcaster 'The Zoo Man', Mr. David Seth-Smith has had unrivalled opportunities for determining what questions relating to mammals and birds most frequently attract public interest. In this book he has selected and answered 324 of them. The result is a very readable volume, crammed with information, illustrated by sixteen mostly good, full-page line drawings (partly by the author and partly by L. R. Brightwell) and provided with a good index

The book can be safely placed in the hands of anybody interested in natural history, for the young will find much to stimulate and the old perhaps many things they did not know before. It would have gained had there been a little more critical proof-reading; for example, antlers are nourished by arteries, and not by veins (p. 31); lemmings go right across Eurasia between Scandinavia and North America (p. 51); the cheetah does not owe its speed to semi-retractile claws—actually, the claws are completely retractile although they are not hidden by special lobes of skin when they are retracted (p. 59); and, of the rook, "the food is very varied . . . and probably only becomes harmful to agriculture when too numerous" (p. 159) is not what the author intended to say.

M. A. C. HINTON

ELECTRON-MICROSCOPIC OBSERVATIONS ON THE XYLEM ELEMENTS OF A FOSSIL PLANT

By A. WESLEY and B. KUYPER*

Botany Department, University of Leeds

DURING the course of preparing sections of petrified plant material by the peel-section method of Walton[1], it was suggested by Dr. R. D. Preston that interesting results might be obtained if such plant remains could be examined in the electron microscope. The object of the present contribution is to record the observations so far made by a technique which we believe to be new to palæobotany. Even these preliminary observations have revealed important details which could not easily have been investigated by any other method. The preparation of fossil material for observation in the electron microscope proved to be unexpectedly difficult, but the following method was finally found to be suitable.

A number of peel sections were made from smoothed surfaces of coal-balls to investigate the state of preservation; but in most cases it was found that, for the present purpose, preservation was incomplete or too poor. However, one specimen contained exceptionally well-preserved material, and it was from this block that the preparations and photographs have been made. The specimen is part of a coal-ball, which was presented to the senior author by the late Prof. W. T. Gordon in 1945. Unfortunately the locality from which it was obtained is unknown; but it is undoubtedly of Lower Coal-Measure age. Running longitudinally through the block is a Stigmarian axis and at right angles to this and to one side is part of a decorticated stem of *Lepidodendron vasculare* (Binney) (= *Lepidodendron selaginoides* Sternberg). Only the woody cylinder of the latter is preserved, measuring about 1·5 cm. long and 1·2 cm. in diameter, with the central primary xylem 0·5 cm. in diameter. A surface was ground in a plane tangential to the *Lepidodendron* stele, and preparations were made from the surface of the secondary xylem so exposed.

The new technique involves the preparation of a section of the plant material by the peel-method and then remounting the section on another film for examination in the electron microscope. Only very thin sections of plant material are of any use, and these were obtained by first dissolving out the calcium carbonate from the smoothed surface of the coal-ball by etching with 2 per cent hydrochloric acid for three minutes. This strength of acid and time of etching were found to be most suitable for this particular material, since the coal-ball contains a high percentage of calcium carbonate. A solution of cellulose nitrate in amyl acetate, of the consistency of pure glycerine, was used for obtaining the 'peels'. Each dried film, containing the imbedded plant cell-walls, was then soaked in dilute hydrochloric acid to remove any particles of rock that might have been pulled off when the film was stripped from the block; after washing well in water, the 'peels' were dried under slight pressure to prevent curling.

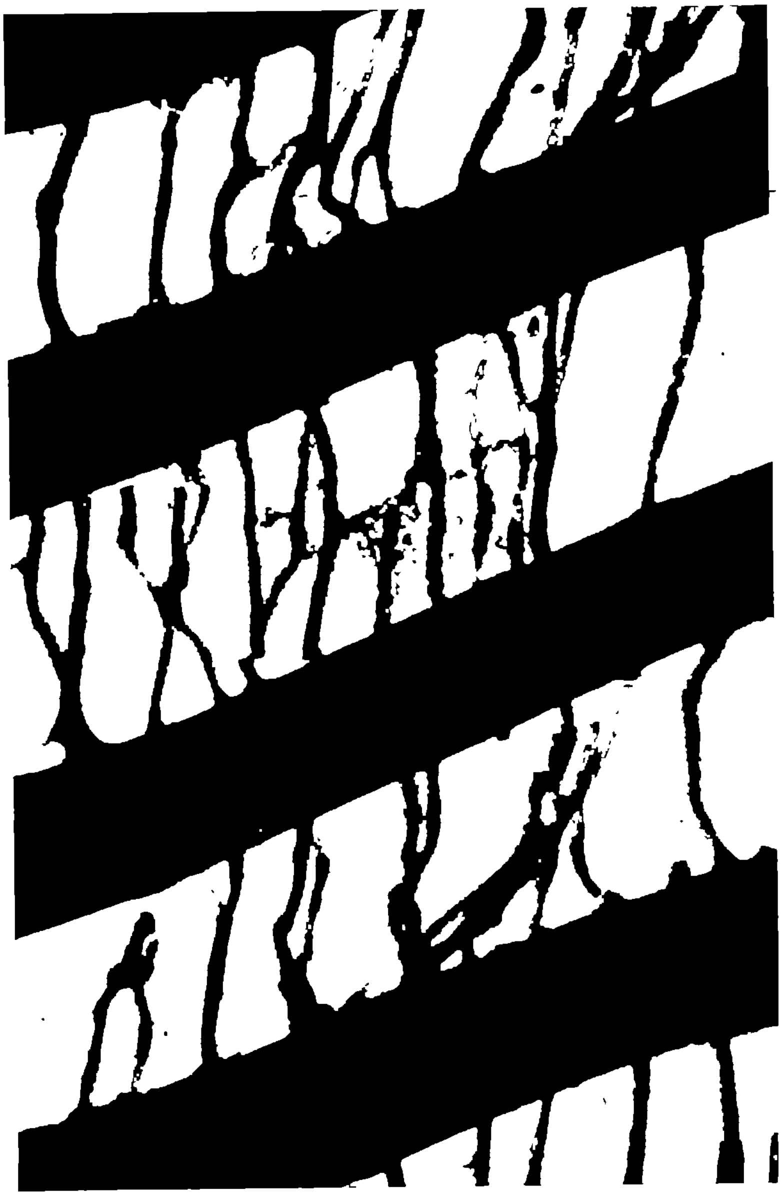

Fig. 1. Portion of a tracheid of *Lepidodendron vasculare* (Binney) showing four transverse scalariform bars and connecting vertical threads (× c 5,450)

---

* On leave from Messrs. Philips Electrical Co., Eindhoven, Holland

The surface of the cellulose film which had been in contact with the rock surface was then covered with a thin layer of 'Formvar' dissolved in dioxan (0·25–0·5 per cent), which was allowed to dry. Selected portions of the double-layered film containing the plant material were cut out and placed on the electron microscope grids with the 'Formvar' surface downwards. The cellulose nitrate was dissolved away with amyl acetate, leaving the plant material standing up in relief and attached to the 'Formvar' film. The preparations were then ready for observation in the electron microscope. The use of cellulose nitrate dissolved in amyl acetate is necessitated since other types of cellulose film partly dissolve when the solution of 'Formvar' in dioxan is applied.

Previous observations under the light microscope have revealed in the tracheids of the xylem of Lepidodendroid plants pronounced scalariform sculpturing of the secondary walls with the transverse bars stretching completely across the wall face. Occasionally the bars may fork; but in general this is not common, and in all cases they merge into a continuous layer at the corners of the tracheids. The bars are slightly narrower at the middle and are spaced at distances rather greater than their breadth. Extending in a vertical direction across the openings between the bars are a number of fine threads which occasionally branch or anastomose with one another by transverse connexions.

This peculiar feature was first described and figured by Williamson[1] in "a scalariform vessel from a Lepidodendroid plant from the coal-measures, probably a *Lomatophloros*" (apparently a misprint for *Lomatophloios*), and he records "a number of delicate vertical lines of lignine, usually simple, less frequently branched, connecting together the contiguous transverse bars of the vessel". Since then, other workers have recorded similar threads in the primary and secondary xylem elements of numerous species of Lepidodendroid plants; but in no case have they ever been observed in any other group of plants either living or extinct.

The following list, which is complete so far as can be ascertained from the records, indicates the range of Lepidodendroid species which exhibit the presence of this unusual structure: *Lepidodendron vasculare* (Binney)[3-6], *L. squamosum* (Göpp.)[3], *L. brevifolium* Will.[7], *L. cf. brevifolium* Will.[8,9], *L. brownii* Unger sp.[10], *L. cf. fuliginosum* Will.[11], *L. johnsonii* Arnold[12], *L. scleroticum* Pannell[13], *Lepidophloios wünschianus* Carr.[8,14], *L. cf. wünschianus* Carr.[11], *L. harcourtii* (Witham)[15], *L. cf. harcourtii* (Witham)[7], *Bothrodendron mundum* Williamson sp.[16,17], *Sigillaria boblayi* Brongn.[18], *Stigmaria ficoides* Brongn.[3,6], *Stigmaria* sp.[19], *Lepidostrobus bertrandi* Zalessky[18], *L. brownii* Unger sp.[20].

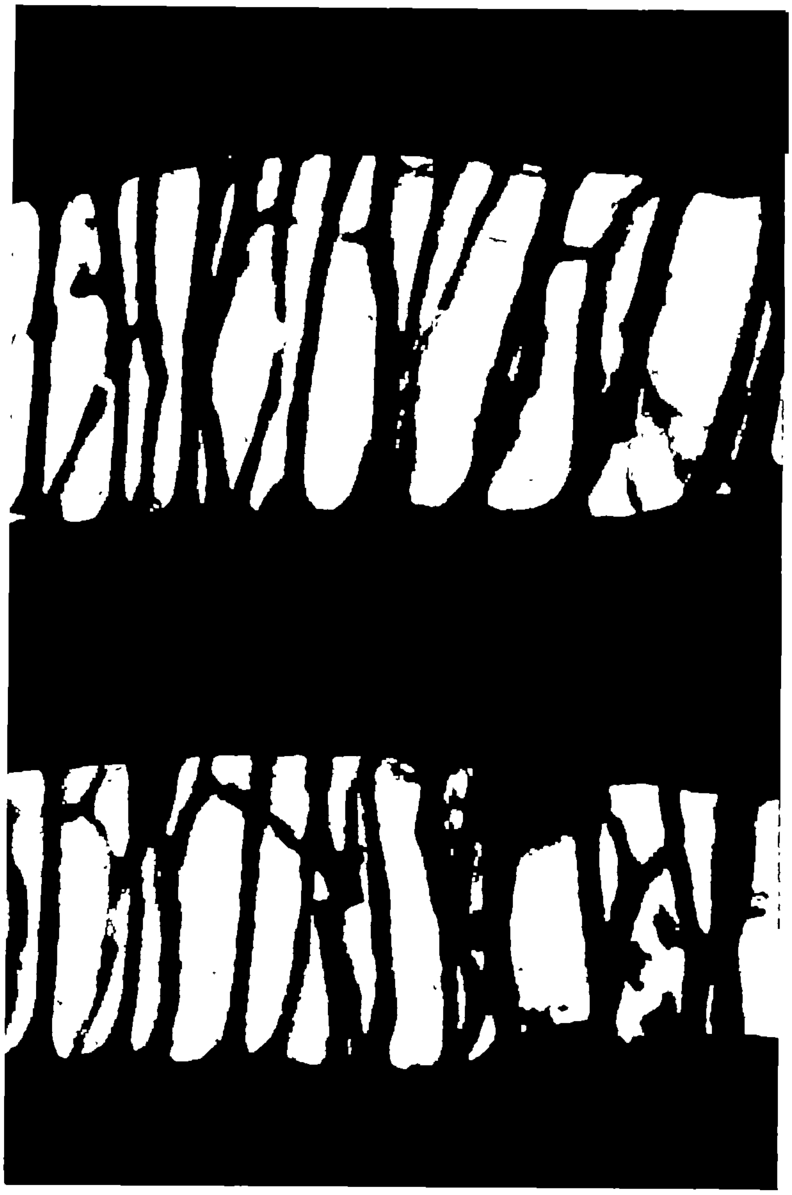

Fig. 2. Similar view of another tracheid (× c. 10,000)

The significance of the series of threads extending across the pit-areas has been discussed by various writers, and divergent conclusions have been reached. It is hoped, in the present contribution, to confirm the generally held opinion that the threads are secondary in nature—the view first put forward by Williamson in 1869 [1].

Seward and Hill[7] suggested that these threads had been formed by the contraction and tearing of the thin membrane which originally connected the scalariform bars. Writing in 1910, Seward[6] added the opinion that the threads probably represent remains of the original wall, which was in process of absorption, but he did not rule out the possibility of post-mortem changes leading to contraction and splitting. On the other hand, Solms-Laubach[3], who also considered the threads to be part of the primary wall, advanced the view that the threads correspond

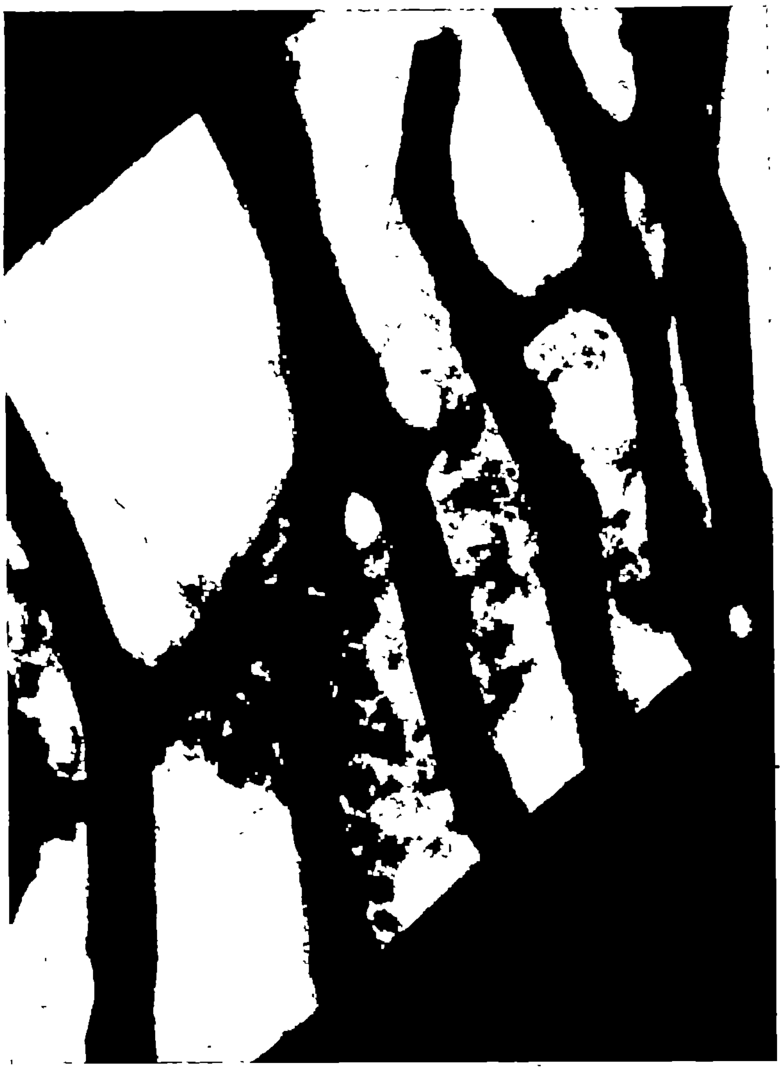

Fig. 3. Part of the tracheid shown in Fig. 1 more highly magnified. To one side a patch of extraneous matter has become entrapped between the vertical threads (× c. 21,800)

to the "*grenzhautchen*" of the tracheid wall, the middle lamella of which had disappeared. Other writers, including Hovelacque[4], Zalessky[10], Duerden[6], Arnold[12] and Pannell[13], have followed Williamson in regarding them as part of the secondary thickenings which lay against the primary wall and bridged the pit-cavity on the inside of the tracheid wall; but Calder[10], at least for *Lepidodendron brownii* Unger sp., considers them as tertiary thickenings laid down in a thin layer around the bars of the scalariform thickenings, with the fine threads connecting the layers.

Figs. 1–3 illustrate the typical appearance of these fine threads in the electron microscope. So far as can be determined from the preparations that have been examined in the electron microscope, there has been no indication of the presence of the original wall stretching between the threads, or of the middle lamella substance between the xylem elements. The absence of such primary wall structures and the isolation in the coal-ball of the xylem cylinder from any cortical tissues leads to the conclusion that the plant must have died prior to preservation, and that all such delicate structures had decayed and disappeared before petrifaction set in. Only the more resistant plant parts, impregnated with lignin, have actually been preserved. This point alone would suggest that the threads are not part of the primary wall, and reference to the figures will dispel the idea that they represent a stage either in a post-mortem change or in absorption of the original wall, since they are too regular and constant in their breadth. Furthermore, Duerden[6] has figured sections of maturing secondary tracheids where the threads are being formed against the inside of the primary wall.

The possibility of their being tertiary in nature still remains, and on consideration it may seem that the threads might not be, in fact, attached to the transverse bars, but to some other layer enclosing the bars. We have, however, never observed such a layer surrounding the bars as was envisaged by Calder, and our preparations have shown that, where the threads have been slightly damaged or completely removed, they leave distinct pegs firmly attached to the bars (Fig. 1).

It seems certain, therefore, that the transverse bars and vertical system of threads are part of one and the same wall structure, and the evidence obtained from our new observations, together with those of certain previous workers, indicates that the series of threads form part of the secondary wall deposits.

In some places (Figs. 1–3), running in a different but parallel plane, two systems of threads are evident which belong to the two neighbouring walls of adjacent tracheids. Examination of the electron micrographs reveals an additional point of interest. The two systems of threads which cross the pit-areas between the transverse bars of adjacent tracheids

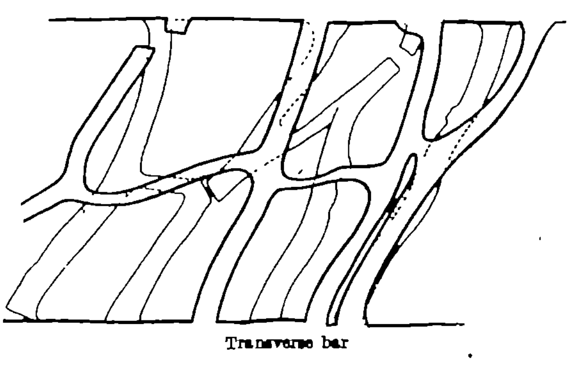

Fig. 4. Diagrammatic representation showing arrangement of two sets of threads on adjacent wall faces The nearer transverse bars and series of vertical threads are outlined more heavily than the corresponding structures of the adjacent tracheid

bear no relation to one another, either in their pattern of branching or at their points of attachment to the transverse bars. The smaller pit-areas which are thus formed between the individual threads do not entirely correspond with a similar region on the wall of an adjacent tracheid and are virtually blind in some parts (Fig. 3). Fig. 4, which has been redrawn from Figs. 1 and 3, shows this point particularly well.

The possibility that any two adjacent series of threads may have become slightly distorted or moved out of alignment with one another during fossilization or preparation of the cellulose nitrate 'peels' is precluded by the very little lateral movement which occurs when fractures break some of the threads. In addition, a number of tracings was made, but in no case was it possible to 'fit' the pattern of any set of threads with the corresponding series of an adjacent tracheid wall.

We are indebted to Dr. R. D. Preston for permission to use the electron microscope provided by the Department of Scientific and Industrial Research, and gratefully acknowledge his advice and help during the course of this investigation.

PHYSICS OF ELECTRICAL DISCHARGE

DURING recent years the mechanism of the electrical breakdown of gases has been a subject of renewed interest. This is due to a variety of causes—in particular, the increasing use of compressed gases as a dielectric with high voltages (as in power cables), and experience with high-voltage machines for research in nuclear and medical physics. Recent work, especially in the United States, on the behaviour of compressed air has demonstrated the surprising fact that the breakdown strength does not increase as the gas pressure increases; this indicates a definite failure of Paschen's law. Increased interest in the mechanism of the electrical breakdown itself has also been stimulated by the desire to obtain a full explanation of the lightning flash.

The initiation and the mechanism of the electrical breakdown of gases was the general theme of a symposium on "Some Aspects of Discharge Physics" which formed the spring provincial meeting of the Physical Society, held at the University College of Swansea during March 29–31. The hundred and fifty scientific workers present, though mainly physicists, included a number of electrical engineers and mathematicians; and a large number of universities, government research establishments, industrial research associations, electrical and other industrial firms were represented at the meeting. The president of the Physical Society, Prof. L. F. Bates, in welcoming the members, pointed out that this was the first visit of the Society to Wales. On the afternoon of March 29 visits were made to the Abbey works of the Steel Company of Wales, and to the Gower Peninsula. On the morning of March 31 a tour of the Department of Physics of the University College of Swansea was made, and of the Sketty Hall Laboratories of the British Iron and Steel Research Association. Altogether, the success of the meeting showed the great interest now felt in discharge physics.

The symposium started with an address by Dr. A. H. von Engel (Oxford) on recent advances in the subject of fundamental collision processes. Examples of ionization by electrons and photons with energies less than the ionization energy were given; mercury vapour can be ionized by low-energy quanta producing two excited atoms which collide to form a molecular positive ion and a free electron. Again, auto ionization is an important cumulative process, for example, in metal vapours: first, two electrons are excited in the same atom, and one of them may then be released if the total potential energy of the atom exceeds the ionization potential. Further, two normal identical atoms may become ionized by collision if their relative velocity exceeds a critical value which corresponds to twice the ionization energy; this has been shown experimentally, and it agrees with classical laws of transfer of energy in collisions. Recent work on ion mobilities was then discussed: the disagreement between theoretical and experimental values of the mobility of positive ions of rare gases moving in their own gas has been found to be due to the formation of molecular ions (for example, He_2^+), which, unlike atomic ions, do not transfer their charges in collisions to neutral atoms. After discussing dissociative recombination, Dr. von Engel concluded by stressing that discharge physics is now entering a most interesting phase.

The next paper, given by Prof. Llewellyn Jones, was on the electrical breakdown of gases. From experimental investigations during the past twenty years, it had widely been concluded that the growth of pre-breakdown currents at high pressures followed a simple exponential law (involving no secondary ionization), and that to account for sparking it was therefore necessary to assume the sudden introduction of an entirely new ionization mechanism (streamer) not related to the growth of initial pre-breakdown currents[1]. This assumption was critically analysed by Prof. Jones, who showed that the experimental data were insufficient to justify such an assumption. The difficult experimental conditions which must be satisfied in order to investigate the problem over the significant range of spark parameters were discussed, and a high-voltage ionization chamber which has been designed and built to satisfy these conditions was described. With this apparatus, measurements have been made at Swansea of pre-breakdown ionization currents for values of the spark parameter ap, which included those corresponding to a 1-cm. gap in the atmosphere[2]. The results show that, while the growth of the currents is simply exponential over the greater part of the sparking distance, in the important region near breakdown itself the currents do, in fact, increase at the faster rate represented by an equation of the Townsend type involving primary and secondary ionization coefficients α and ω. This indicates that the mechanism of the spark itself is the same as that which leads to the growth of the photo-current even in its early stages ($i \sim 10^{-15}$ amp.). Possible secondary ionization processes were discussed in the paper—such as the ionization of gas atoms by photons, or by collision through the agency of positive ions involving electron transfer and the production of fast neutral atoms[2]; and also the cathode processes of secondary emission by positive ions or by photons. It was stressed that the essential feature of the breakdown mechanism is the development of the avalanche from behind by a secondary generating cause moving towards the cathode, a process which is most efficient when it acts at the cathode itself. Evidence was also given for the existence of secondary emission from the cathode by the impact of positive ions even with spark voltages up to 30 kV. W. Hopwood (Liverpool) then followed with a paper on the positive streamer mechanism. He pointed out that, in view of the experimental results of Llewellyn Jones and Parker[3] and recent work in the United States[4] on the formative time-lag of sparking in the important region near breakdown, some modification of the original streamer type theory is now required.

There was active discussion of these papers. C. G. Morgan (Swansea) dealt with the failure of Paschen's law at high voltage[5], and indicated that the intervention of cold-cathode field-emission is sufficient to explain this failure and also some experimental results of his own. R. Fortescue (Queen Mary College, London) raised questions on the interpretation of photographs of anode and mid-gap streamers, on instability at breakdown and on the physical explanation of the influence of the cathode on breakdown at very high pressures. E. H. Cohen described recent high-voltage work done at Queen Mary College employing gas pressures of 1,000 lb./sq. in. S. Haydon (Swansea) gave theoretical considerations of photo-ionization in the gas; preliminary calculations with Dr. P. M. Davidson suggest that such processes do not predominate in the spark mechanism in air at high pressure; but for detailed calculations further numerical data on absorption cross-sections are required. J. Dutton (Swansea) discussed the interpretation of the results of recent work on formative time-lags[4], and showed that these are fully consistent with modern work on the growth of pre-breakdown currents, described above, and with the explanations proposed, concluding that a streamer mechanism is both insufficient and unnecessary to explain these results.

The session on March 30 opened with a paper by C. G. Morgan (Swansea) on the cold emission of electrons and discharge initiation. Cold emission from various electrode surfaces in air at atmospheric pressure under fields of the order of 10^4 volts/cm. has been found to depend strongly upon the nature of the electrode surfaces: thin oxide films or microscopic insulating particles give rise to enhanced electron emission[6]. Experiments have shown that the emission follows a field law. The role of post-breakdown residual positive ions in initiating succeeding sparks has also been examined, and it is concluded that a surface charge of positive ions on an insulating film at the cathode can give rise to enhanced field emission. This effect can lead to failure of Paschen's law. R. D. Craig (Metropolitan-Vickers Electrical Co., Ltd.) described experiments on the production of electrode vapour and its effects on the afterglow: 10 μsec. high-current pulse discharges were employed with electrodes of magnesium, copper, iron, carbon and tungsten. The observed large transport velocity of electrode material can only be explained if it leaves the electrode in the form of droplets or liquid jets.

In the discussion which followed, J. C. S. Shaw (Cambridge) pointed out that Mr. Morgan's views are consistent with present knowledge of backfires in rectifiers[7]. W. D. Chesterman (Admiralty Research Laboratory) described some of his experiments on the production of light flashes by the discharge of a condenser through a sealed quartz tube. G. G. Isaacs (G.E.C. Research Laboratory, Wembley) outlined work on high-pressure mercury vapour discharges, and showed that the cathode may give rise to effects extending far beyond what is usually regarded as the cathode region at these high pressures.

In the afternoon of March 30 there were four papers on high-frequency discharges. Dr. G. D. Morgan (University College of North Wales, Bangor) discussed breakdown and described experiments at Swansea made in hydrogen at low pressures p and at frequencies f between 5·0 and 70 Mc./s. to test the validity of a general similarity theorem: $V_s = \varphi(ap, f/p)$. The theorem holds accurately for breakdown, but less accurately for maintained high-frequency currents—this he attributed to discharge instability. G. Francis (Oxford) has found that the growth of electrodeless discharge at low pressure proceeds in three stages: the first stage is a multiplication of electrons by secondary emission from the glass walls of the vessel; the second is the production of a distributed positive space-charge of gas ions with a maximum at the centre of the vessel; finally, an equilibrium state is established when the production of ions and electrons in the gas equals the losses to the walls. A new technique has been used, and oscillograms showed how the growth of the discharge depends on the pressure and on the gas. W. L. Harries (Oxford) described the mechanism of the low-frequency electrodeless discharge in chlorine, and the influence of irradiation. He has found that the current consists of pulses, the number increasing with the voltage: each pulse corresponds to a series of electron avalanches developing between small areas of the inner glass surfaces. G. C. Williams (Swansea) described his work on the similarity theorem and corona relationship for both static and high-frequency discharges in air, hydrogen and monatomic gases; he also discussed the mechanism of the static corona discharge.

The symposium concluded with a paper by Dr. Elwyn Davies (Swansea) on the breakdown mechanism in static discharges at low pressures. He has examined the dependence of the shape of the cathode emission (ω/α) curves on the deposition of electro-positive or electro-negative atoms on cathodes of nickel, aluminium, silver, copper and molybdenum. Deposition of electro-positive atoms on the cathode produces sharp photoelectric peaks in the curves in the region $X/p \simeq 150$ V./cm. × mm. pressure of mercury; but at higher values of X/p the quantity (ω/α) is not greatly affected. Dr. Davies analysed these results in terms of the varying effective work function of the surface due to the deposition of atoms. He concluded that in hydrogen the high photoelectric emission from cathodes of low effective work function is due to low-energy photons generated in the pre breakdown currents, but that for clean metals the secondary emission is due almost entirely to the impact of positive ions; photoelectric emission due to any high-energy photons generated in the ionization currents is negligible in comparison. Thus the breakdown process is almost completely determined by the nature of the cathode surface. The succeeding discussion included contributions from Prof. J. M. Meek (Liverpool) and J. R. Acton (Ericsson Telephones, Ltd.).

REPORT OF THE COMMITTEE ON WEIGHTS AND MEASURES LEGISLATION

SOME important recommendations, of widespread interest, emerge from the deliberations of the committee appointed by the President of the Board of Trade to review the existing weights and measures legislation and administration in Great Britain. The report* presents the results of the first full inquiry into this subject since that of the Standards Commission of 1867–70. Not unnaturally, in view of the large amount of legislation which has since been effected, the recent committee, under the chairmanship of Sir Edward Hodgson, advocates a consolidation of the law in regard to weights and measures; but the chief scientific interest lies in Part 1 of the report, dealing with the units and standards of measurement. Foremost among the items of Part 1 is the recommendation that the Imperial system of units should eventually be abolished in favour of the metric system. This recommendation is unanimous and, as the committee says, contentious in the extreme. It visualizes a lengthy period to prepare the general public for the change and to provide schemes for the change-over, trade by trade, during a transition period extending over twenty years or more. But, above all, the recommendation is conditional on an approach being made to the Commonwealth and the United States, so that all may move together, or not at all.

When the Commission of 1867–70 examined this question, it recommended that the use of the metric system concurrently with the Imperial should be permitted for the purpose of trade. As a result of this recommendation, provision was made for the use of approved metric standards of weight and measure. In 1870 the metric system was compulsory in fifteen countries, but when the Hodgson Committee approached the matter, the number of such countries in the world had increased to fifty-five, the outstanding exceptions being the Commonwealth and the United States, which together conduct half, if not more, of the world's trade, using chiefly the yard–pound system. In the face of conflicting external factors and the mixed evidence submitted, the Committee found no easy solution. The real problem before it was whether to maintain two legal systems or to take steps to establish world-wide uniformity by changing completely to the metric system. The Committee, while bearing in mind the well-known objections to the change and in particular the difficulty of altering the units of measurement in the engineering and other industries, has resisted the arguments in favour of retaining the present concurrent use of both systems and has laid more stress on the part to be played by Great Britain in the international affairs of the future, in trade and commerce, defence, etc. The future needs of the country are not easily assessed, but at no time have smooth international dealings been so important as at present.

Much has been said on the subject by pro- and anti-metricists, as for example at the discussion at the British Association meeting in Brighton in 1948. It is hoped that any differences of opinion as to the Committee's recommendation will rise above the usual retorts as to the relative shortcomings of this or that set of units and reach a level where the significant factors are disentangled from the irrelevant. Looking back over a hundred and fifty years since the initiation of the metric system, we cannot close our eyes to its advance; and there is no indication that the trend towards its universal adoption has been reversed. It remains to be seen whether the Committee's long-term view on this subject will eventually receive sufficient support to overcome the inherent objections to the change.

The Committee, in making this recommendation, also envisaged the decimalization of the coinage, but this matter was considered to be outside its terms of reference. As a shorter-term proposal of the wider project, the Committee recommends that the apothecaries, troy and pennyweight systems of measurement should be abolished after five years and replaced by the metric system. This, though it might be regarded as a 'thin end of the wedge' for the long-term project, has the obvious advantage of removing from the Imperial system much unnecessary complexity of units; moreover, metric weights are normally used in scientific work.

Whether the long-term proposal to change to the metric system is accepted or not, strong support should be forthcoming for the recommendation that the independence of the Imperial and metric units of length and mass should be terminated, and that the yard and pound should be defined in law as definite fractions of the international metre and kilogram respectively. This proposal was put forward in 1946 by the British Empire Scientific Conference and has two main objects. The first is to remove embarrassments arising from the existing situation and particularly those caused by variations from time to time in the relationship of the material standards of the yard and the metre to one another, and also those of the pound and kilogram. The effect of the slight progressive shortening of the Imperial Standard Yard is sufficient to be felt in high precision measurements with engineering standards and in the surveying field. The second object is to eliminate the small differences which exist between the Commonwealth and the American yards and pounds. The differences have arisen because these units have been defined in Britain by reference to independent standards, whereas in the United States, ever since 1866, they have been defined by fixed ratios to the metre and kilogram respectively. The Committee recommends the general adoption of the principle of fixing the yard/metre and pound/kilogram ratios, and proposes to apply it in a most rational manner to bring the Commonwealth and American yards and pounds into equality. The definitive values recommended are as follows: 1 yard = 0·9144 metre (corresponding to 1 inch = 2·54 centimetres exactly); 1 pound = 0·453 592 37 kilogram or 0·453 592 3 kilogram.

---

* Board of Trade. Report of the Committee on Weights and Measures Legislation. (Cmd. 8219.) Pp. iv+147. (London: H.M. Stationery Office, 1951.) 3s. 6d. net.

With the view of their adoption in the Commonwealth and the United States, the Committee suggests that the Government of the United States be informed of these proposals. This is a worthy project which should be strongly pursued between the countries concerned. Scientific workers generally, and metrologists in particular, will support the proposal.

In connexion with the legal definitions of units and standards of measurement used in Great Britain, it has been found that these are not always satisfactorily prescribed in an Act of Parliament. An element of flexibility is essential to enable British practice to keep abreast of the latest technical developments and international agreements, and for various purposes the Committee recommends suitable machinery for effecting changes whenever the need arises. This machinery is based on the principle of delegated powers of legislation to be exercised by the Minister within the broad purposes of an Act. In order to provide satisfactorily for definitions in law of certain units, for example, those of time, capacity, temperature, heat and electricity, together with the prescription of standards for such units, and associated matters, it is proposed that a permanent commission be appointed by the President of the Board of Trade to advise on such subjects. The Committee has in mind a strong and wide advisory basis for this work and suggests that the commission should consist of the Astronomer Royal, the director of the National Physical Laboratory, the president of the Royal Society, two members nominated by the Lord President of the Council, one by the Lord Chancellor, and the chairman and not more than three other members by the President of the Board of Trade. It is recommended that the President of the Board of Trade be empowered to give effect by subordinate legislation to the recommendations of the commission and required to lay before Parliament at appropriate intervals a report on its work.

Concerning the more general conclusions to which the inquiry has led, the Hodgson Committee is satisfied that the existing principles of weights and measures law are soundly based and stand in no need of fundamental revision. They have provided a reasonable protection to all engaged in trade, and the machinery of administration appears to have worked well over the years. In the remaining parts of the report, recommendations of varying scope and importance are made in regard to weighing and measuring equipment and the protection of the public against the giving of short weight or measure; but, in the main, these proposals represent additions to, or simplifications of, the present framework, rather than completely novel features. It is recommended that the administration of weights and measures law should continue to be in the hands of local authorities, but should be entrusted in future only to those larger authorities the work of which would require the employment of at least three inspectors. On this basis there would be eventually about a hundred and forty weights and measures administrative units in place of the 258 at present, and more economical use of staff could justifiably be expected from such a change. As in the past, the Board of Trade through its Standards Department should bear the ultimate responsibility for ensuring efficiency. The main duties of the Department are defined, with a recommendation that its name be changed so as to avoid confusion with the British Standards Institution, which, as is well known, deals with standards from another aspect.

It is hoped that, whenever there is general agreement that the Committee's recommendations are wise and can be implemented without much upheaval, they will be put into effect with reasonable promptitude. In particular, the redefinition of the yard and pound in terms of the metre and the kilogram is a reform long overdue, which should not be delayed on account of other recommendations which may appear controversial or involve major difficulties.

F. A. GOULD

OBITUARIES

Prof. Alexander McKenzie, F.R.S.

WITH the death of Prof. Alexander McKenzie, emeritus professor of chemistry in the University of St. Andrews (University College, Dundee), on June 11, at the age of eighty-one, another link has been severed with the great classical age of organic chemistry.

McKenzie was the son of a village schoolmaster in Angus and received his early education at the High School, Dundee. He entered the United College, St. Andrews, in 1885 and laid a sure foundation for his liberal outlook of later life by reading for the M.A. degree before embarking upon his studies in chemistry. The thrill of research soon captivated him, and after working under Thomas Purdie for a while he gave up, at considerable personal sacrifice, his lectureship at the United College to work with Marckwald in Berlin. His Ph.D. thesis there was a masterpiece which has become a classic. Shortly afterwards he graduated D.Sc. of St. Andrews and embarked on his teaching career, first in London and then in Birmingham, where he became special lecturer in organic chemistry. In 1905 he was appointed head of the Chemistry Department in Birkbeck College, London, a post which he held with such distinction that he was the obvious choice for the chair in his native Dundee when this fell vacant at the end of 1913.

During 1914–38 McKenzie was professor of chemistry in University College, Dundee. His researches expanded and developed throughout the field of stereochemistry, and his reputation became worldwide. At home the merit of his work was recognized by his election in 1916 as a Fellow of the Royal Society, and in Germany by the rare distinction of his admission as an Honorary Fellow of the Kaiserlich Deutsche Akademie der Naturforscher, Halle. On his retirement he received the LL.D. of St. Andrews.

McKenzie's research work was mainly concerned with stereochemical problems, in particular as applied to the derivatives of mandelic, tartaric, malic, maleic and fumaric acids. The isolation of the optically active forms of benzoin and his work on catalytic racemization are examples of his early pioneering. A clear appreciation of the factors leading to loss of optical activity enabled him to devise and carry out the first asymmetric synthesis of mandelic acid; and this was followed by further successful syntheses of the same kind. McKenzie will also be remembered for his work on the Walden inversion, which also led to the investigation by polarimetric methods of the deamination reactions of α-amino-alcohols and the accompanying migration of organic radicals. These topics provided material for a long series of important researches. All his work was characterized by a subtle elegance which led one of his colleagues to comment that "in attacking the refined secrets of the organic molecule he discarded the ponderous weapons of men of grosser mould for the light rapier of the 'chymicall Artist' ".

McKenzie also possessed an acute faculty for the appraisal of work besides his own, as witnessed by his early applications of the Grignard reaction. Furthermore, he had the philosophical and cultural outlook characteristic of the scientific men of his generation, an outlook which is so often lacking to-day.

He was an inspiring teacher, and during his twenty-five years in Dundee he trained a steady stream of research students. He took a lively and enduring interest in the personalities and progress of his pupils, an interest which he maintained throughout his years of retirement. His enthusiasm for the progress of organic chemistry never flagged, and he insisted on reading every new thesis on organic chemical topics originating from the Department.

He is survived by Mrs. McKenzie and their son.

D. H. Everett

We regret to announce the following deaths:

Sir Walter Johnson, C.M.G., director of medical and sanitary services in Nigeria during 1929–36, known for his work on trypanosomiasis and yellow fever, aged sixty-five.

Commissioner David Lamb, C.M.G., LL.D., director of the Salvation Army Emigration Department during 1903–30 and known for his social studies, who frequently attended meetings of the British Association, on July 7, aged eighty-four.

Mr. William Lowson, formerly senior lecturer in analytical chemistry in the University of Leeds, with which he had been associated since 1897, on May 20.

Prof. H. Nagaoka, professor of physics in the University of Tokyo during 1896–1926, on December 10, 1950, aged eighty-five.

Dr. John Rickman, sometime president of the British Psychological Society and for many years editor of the Society's *Journal*, aged sixty.

NEWS and VIEWS

Institute of Navigation: Thurlow Award

Dr. E. G. Bowen, chief of the Division of Radiophysics of the Commonwealth Scientific and Industrial Research Organization, Sydney, has been given the Thurlow Award for 1950 of the Institute of Navigation, of the United States, for his outstanding contribution to scientific navigation during the past year. The Award is a memorial to Colonel Thompson L. Thurlow, formerly chief of the Navigation and Instrument Section of the Equipment Laboratories of the United States Air Force at Wright Field, Dayton, Ohio, who was killed in 1944. Dr. Bowen and his co-workers have developed several new radio navigational aids which are of special importance in aviation. Their distance-measuring equipment (D.M.E.) has been adopted for civil airline use in Australia. For the first time it provides the pilot of an aircraft with an instrument showing his distance from an airport he is approaching. Another system they have developed, multiple-track radar range (M.T.R.), enables aircraft to fly on a series of tracks radiating from an airport. It has aroused considerable interest in aviation circles overseas. Their latest device is a microwave navigational system which provides a radio counterpart to the simple visual method of navigation using beacon lights. It enables the pilot to 'see' and use radio beacons in thick weather in as nearly as possible the same way that ground markers or light signals can be used as navigational aids under conditions of perfect visibility. It offers great promise as a navigational system for use by aircraft where it is uneconomical to provide the elaborate facilities used on main air routes, and for use by ships in confined waters.

Dr. W. J. V. Osterhout

Dr. W. J. V. Osterhout, the well-known American botanist, will celebrate his eightieth birthday on August 2. Dr. Osterhout has, since the beginning of the century, established himself as one of the world's authorities in plant physiology, especially cell physiology, working mainly in the University of California and Harvard University until 1925, when he transferred to the Rockefeller Institute, New York. From there he retired when he reached his seventieth year; a note of appreciation was published in *Nature* at that time (147, Jan. 25, 1941). Dr. Osterhout has trained or inspired workers in the subjects of his choosing in all parts of the world. We should like to join all those in congratulating him on this occasion and to express the hope that he will long continue to exert his powerful influence and encouragement.

Royal Society Research Fellowships

Dr. C. E. Lumsden, of the University of Aberdeen, has been appointed second Henry Head Research Fellow of the Royal Society from October 1, to work at the Maida Vale Hospital for Nervous Diseases and the National Hospital for Nervous Diseases on disseminated sclerosis. The Council of the Royal Society has appointed Dr. D. R. Wilkie to be the first Locke Research Fellow, from October 1, to work at University College, London, on energy relations in muscular contraction. Frank Spiller Locke, formerly reader in physiology at King's College, London, who died in 1949, left part of his estate to the Royal Society for the endowment of Locke research fellowships in experimental physiology and pharmacology. The Council has also appointed for the first time two Stothert Research Fellows, each for two years in the first instance, from October 1. Mr. J. R. Vane will work at the Nuffield Institute for Medical Research, Oxford, on the mechanism by which histamine produces gastric secretion, and Mr. J. M. Walshe will work at University College Hospital, London, on amino-acid metabolism in liver disease. The Stothert Research Fellowships are established by the bequest to the Royal Society of the residuary estate of Dr. John Henry Stothert, lecturer in pharmacology at University College

Hospital, who was drowned at the age of twenty-seven in a canoeing accident in Austria in 1937; the bequest came to the Society in 1948 after the death of Lady Stothert.

Agricultural Machinery at the Science Museum

The collections of agricultural implements and machinery at the Science Museum, started in 1857, contain a fine historical series from which a selection has been made for public exhibition. They were taken to the country for safety in 1939 and it is only now possible to show them again to the public. The present display occupies the first floor of a building block of which the frame, with temporary wall panels, was constructed before the War as a part of the original East Block, but not completed and furnished until now. In this, the first section of the newly finished museum building to be opened, daylight has been excluded and by use of controlled fluorescent lighting it has been possible to incorporate several novel methods of display. These, while avoiding the transience of the display methods now common in trade exhibitions and the like, have nevertheless been devised with the view of the maximum visual appeal. Recent developments have been shown by means of a series of nearly a hundred models, all to a scale of one inch to a foot, contributed by some twenty firms in the industry. These are displayed against scenic backgrounds with plaster bases and illustrate the work of the up-to-date mechanized farm throughout the seasons of the year. As a centre-piece there is a full-sized sectioned and working combine harvester. Other full-size exhibits include early ploughs, a horse wheel, Bell's reaper of 1826 and the Ivel farm tractor of 1902, the first medium-powered farm tractor driven by an internal combustion engine. In the space at present available it has only been possible to deal with arable farming. The display has been planned in close consultation with the Ministry of Works, which has been responsible for the design and provision of the building, lighting, display cases, etc.

Gas Council Research Centre at Birmingham

The Gas Council has set up a second research centre at the Nechells Gasworks, Birmingham, the work of which will be mainly concerned with the complete gasification of coal. This centre will be administered by the West Midlands Gas Board on behalf of the Gas Council, and its director will be Dr. F. J. Dent, at present assistant director of the Gas Research Board. Dr. Dent has been closely concerned with the experiments upon complete gasification which have been conducted at the Poole Research Station. Great importance is attached to this particular field, and the Gas Council has decided that this work can be accelerated at Birmingham where there are far greater facilities than at Poole, although this does not mean that the work at Poole will cease.

Expedition to Chubb Crater in Northern Canada

The National Geographic Society and the Royal Ontario Museum, Toronto, are sending a joint expedition to far northern Canada to explore the recently discovered Chubb crater. Dr. Victor Ben Meen, a well-known Canadian geologist and director of the Museum, will lead the expedition. The crater site is in northern Quebec between Hudson Bay and Ungava Bay, and the expedition, which is travelling by air, expects to land on a near-by ice-free lake and make camp as near the boulder-strewn crater as is possible. The crater is more than two miles wide and hundreds of feet deep, surrounded by a rim averaging 400 ft. high. Dr. Meen saw the crater last year when he surveyed the area in the company of Frederick W. Chubb, a prospector who discovered it, and after whom it is named. Its appearance suggested a tilted cup with one side considerably higher than the other. It is thought that the crater may have been caused by the fall of a meteorite. The expedition is taking modern scientific equipment and will attempt to ascertain the origin of the crater.

Courses and Examinations for Instrument Maintenance Mechanics

The City and Guilds of London Institute has recently announced the adoption of a new scheme of courses and examinations in instrument maintenance (Subject No. 79). The scheme, which has been drawn up by an advisory committee representing a wide range of interested bodies, is intended for mechanics and technicians concerned in the maintenance, repair and installation of the instruments used for process and production control in industrial plants and in the Armed Services. Particular attention has been given to the requirements of the chemical, iron and steel, and petroleum industries, to fuel economy, and the needs of the Services; but the structure of the scheme is such that it will have wide application. The courses consist of five years of part-time study at a technical college, with an intermediate examination at the end of the third year, and a final examination at the end of the fifth year. There is provision for students holding an appropriate Ordinary National Certificate to enter the course at the beginning of the fourth year. It is hoped that by the provision of these courses the serious shortage of skilled instrument mechanics which is at present handicapping British industry will be effectively reduced. Further details of the scheme, including a pamphlet containing the regulations and syllabuses for the City and Guilds examinations (available shortly, price 6d.) can be obtained from the Department of Technology, City and Guilds of London Institute, 31 Brechin Place, London, S.W.7.

A Pioneer in Modern Farm Practice

A recent number of the magazine *Scotland* (No. 52, June 1951) includes an article extolling the important contributions made by scientific men from Scotland, and in particular from Glasgow, to the development of the industrial revolution and of the atomic age. While these are, for the most part, well known, the author, Prof. Hugh Nicol, of the West of Scotland Agricultural College, also places on record the interesting fact that at the commencement of the nineteenth century a Glasgow citizen, William Harley, author of "The Harleian Dairy System" (1829), ran an internationally famous dairy farm in Glasgow. In the dairy, which held two hundred cows, of which a careful register was kept, there was a steam engine which operated machines for turnip-slicing, chaff-cutting and churning. This machine was in operation in 1814 and possibly as early as 1812, in the same year, as Prof. Nicol puts it, that the famous steamship the *Comet* first sailed on the Clyde; it is claimed to be the earliest known instance of the use of steam for agricultural purposes.

Representation of Snow in Museum Displays

The standards of modern display make great demands on the museum curator, who is constantly called upon to reproduce natural environments of various types. Perhaps a snow scene is one of the most difficult to construct, and its realism is often marred, not least by streaks of dust. In the December 1950 issue of the *Museums Journal*, W. T. Stirling, of the Royal Scottish Museum, Edinburgh, describes, with operational details, a method by which 'snow' is made from paraffin wax. Molten wax is sprayed with considerable force on to the surface of cold water contained in a large sink, and from a distance which confines the wax particles to the water surface. The accumulating solidified particles are periodically removed and placed in a fine-meshed sieve to drain. Finally they are heaped on to the exhibit. This method obviates any surplus wax on the specimens or the case, and has the advantage that the 'snow' may be arranged in any way, and may be re-arranged if soiled by dirt. The characteristic sparkle may be obtained by liberally sprinkling with thinly blown and finely fractured glass.

Heriot-Watt College, Edinburgh: Award of Fellowships

THE governors of the Heriot-Watt College, Edinburgh, have instituted a new award, namely, fellowship of the College, designed primarily to encourage original work in those branches of study at present recognized for the associateship of the College, namely, mechanical and electrical engineering, applied chemistry, mining engineering, brewing and fermentation industries. The fellowship is open to (*a*) an associate of the College of not less than five years standing, who presents a thesis embodying the results of original research carried out since leaving the College; (*b*) associates or others holding equivalent qualifications, who complete a period of advanced study in the College and present a thesis. The governors of the College also have powers to confer the honorary fellowship on persons distinguished in science or engineering connected with the College. It is hoped that the institution of this award will in due course give an impetus to the extension of the research activities and higher technological training in the College, and so enable it to play an ever-increasing part in developing industrial productivity.

On July 10, the Lord Provost of the City of Edinburgh, the Right Hon. James Miller, conferred the honorary fellowship of the College on the following old students, former members of staff and governors of the College: John M. Caldwell, general manager, Scottish Oils, Ltd.; Prof. Raymond G. H. Clements, emeritus professor of highway engineering, Imperial College, University of London; Major-General David R. Duguid; Dr. Charles Forrester, deputy chief-fuel engineer, Ministry of Fuel and Power; Prof. James Greig, William Siemen's professor of electrical engineering, King's College, University of London; Wm. Hamilton Gray, senior partner with the firm of McKerrell Brown & Gray; Prof. Alex. R. Horne, emeritus professor of mechanical engineering, Heriot-Watt College; Dr. Edward Hughes, vice-principal, Brighton Technical College; J. Morison Inches, managing director of J. & J. Morison, Ltd.; Peter Kerr, technical secretary of the Institute of Petroleum; Henry R. King, production director, Scottish Division, National Coal Board; James M. Mackintosh, formerly organizer of further education under Edinburgh Corporation Committee; Dr. Wm. Maxwell, until 1949 managing director of Messrs. R. & R. Clark, Ltd.; Dr. Christina C. Miller, lecturer in chemistry, University of Edinburgh; Dr. David Penman, formerly principal, Indian School of Mines; Dr. John S. Penman, vice-principal, Barnsley Technical College; Dr. Willison B. Peutherer, manager, Grangemouth Refinery, Scottish Oils, Ltd.; Dr. James Sandilands, assistant professor, Heriot-Watt College; Roderick M. Shearer, formerly head of the Mathematics Department, Heriot-Watt College; Dr. James Cameron Smail, emeritus principal, Heriot-Watt College; Dr. Alex. M. Smith, head of the Department of Chemistry, College of Agriculture, Edinburgh; Dr. John B. Tait, senior principal scientific officer, Marine Laboratory, Scottish Home Department, Aberdeen; Dr. J. Albert Thomson, chairman and managing director, Brown Bros., Ltd., London; Wm. Watson, formerly head of the Physics Department, Heriot-Watt College; Robert Wilson, director, Pillans & Wilson, Ltd.

National Radio Exhibition

THE term 'Radiolympia' has in the past become well known to all those who are interested in the exhibition organised and held in London under the auspices of the Radio Industry Council. This year, circumstances have necessitated a change of name to that of National Radio Show, and it will be held at Earls Court during August 29–September 8. In connexion with this exhibition, a very interesting and well-produced booklet has recently been issued by the above Council. It is entitled "British Radio and Television for the World—London 1951"; and is intended to interest the overseas reader who will be visiting Great Britain in connexion with one or other of the several exhibitions being held in the early autumn of this Festival of Britain year. The contents of the booklet deal with the current state and trends of technical development in the fields of television, radio and sound reproduction, communications and navigational aids, electronics, including equipment for industrial, medical and scientific purposes, and with valves, cathode ray tubes, components and accessories. All these subjects are illustrated by many interesting photographs, including views of the Birmingham television installation and an associated relay station, the sound-reproducing arrangements in the new House of Commons and, literally, a thimbleful of sub-miniature valves. Copies of the booklet are obtainable on application to the Secretary, Radio Industry Council, 59 Russell Square, London, W.C.1.

Royal Meteorological Society: Officers

THE following have been elected officers of the Royal Meteorological Society for the year 1951–52: *President*, Sir Charles Normand; *Vice-Presidents*, Wing-Commdr. Poulter, Dr. R. C. Sutcliffe, Sir Robert Watson-Watt, W. M. Witchell; *Vice-President for Canada*, A. Thomson; *Vice-President for Scotland*, Sir Ernest Wedderburn; *Secretaries*, Prof. P. A. Sheppard, R. G. Veryard; *Treasurer*, Prof. G. C. McVittie; *Editor*, Prof. P. A. Sheppard. The new session will begin on October 1.

University of London: Appointments

THE following appointments have been made in the University of London: Dr. K. A. Hirsch, to the University readership in mathematics tenable at Queen Mary College; Mr. J. K. T. L. Nash, to the University readership in civil engineering tenable at King's College; Dr. Stanley Rowlands, to the University readership in physics tenable at St. Mary's Hospital Medical School.

The title of professor emeritus in the University has been conferred on the following in respect of the chairs they have held at the colleges mentioned: Prof. M. E. Delafield (chemistry as applied to hygiene, London School of Hygiene and Tropical Medicine); Prof. H. F. Hallett (philosophy, King's College); Prof. M. F. Lucas Keene (anatomy, Royal Free Hospital School of Medicine); Prof. J. R. Partington (chemistry, Queen Mary College); Prof. A. V. Hill (physiology and head of the Biophysics Research Unit, University College); Prof. D. M. S. Watson (Jodrell chair of zoology and comparative anatomy, University College); Prof. H. E. Watson (Ramsay chair of chemical engineering, University College).

The following doctorates have been conferred: *D.Sc.:* Mr. W. B. Mann (Imperial College of Science and Technology); *D.Sc.(Econ.):* Mr. R. H. Coase (London School of Economics and Political Science).

Colonial Service: Recent Appointments

THE following appointments have recently been made in the Colonial Service: J. Cofie (senior agricultural officer, Gold Coast), senior assistant secretary, Gold Coast; N. Lamont (agricultural officer, Fiji), economic botanist, Fiji; G. M. Roddan (director of agriculture, Nyasaland), director of agriculture, Kenya; J. O. Torto (assistant director of agriculture (cocoa industry, temporary), Gold Coast), senior assistant secretary, Gold Coast; W. T. S. Brown (conservator of forests, Gold Coast), deputy chief conservator of forests, Gold Coast; D. A. Cannon (senior pathologist, Nigeria), assistant director of laboratory services, Nigeria; A. Kertesz (medical officer, Nigeria), pathologist, Nigeria; Dr. J. Anderson (senior veterinary research officer, Kenya), assistant director of veterinary research, Kenya; G. D. N. Bartlett (agricultural assistant, Nyasaland), principal agricultural assistant, Nyasaland; R. Elliott (entomologist, Sierra Leone), entomologist, Nigeria; C. D. Hutchings (senior agricultural officer, Jamaica), deputy director of agriculture (Extension Services), Jamaica; F. F. Smithyman (agricultural assistant, Nyasaland), principal agricultural assistant, Nyasaland; Dr. R. A. Kenney, senior scientific officer (physiologist), Heat Research Unit, Nigeria; D. A. Brown, veterinary officer, Kenya; P. D. Berwick, meteorologist, East Africa High Commission; H. T. Hayes, fisheries officer, East Africa High Commission; A. B. Law, meteorological officer, Northern Rhodesia; R. T. Smith, sociological research officer, British Guiana; J. E. Stevens, senior meteorological officer, Northern Rhodesia; T. Trimble, meteorological assistant, East Africa High Commission; W. R. Bransby-Williams, field officer, Colonial Insecticides Research Unit, East Africa.

The Night Sky in August

NEW moon occurs on Aug. 2d. 22h. 39m., U.T., and full moon on Aug. 17d. 02h. 59m. The following conjunctions with the moon take place: Aug. 1d. 04h., Mars 3° S.; Aug. 5d. 07h., Mercury 2° S.; Aug. 5d. 21h., Venus 4° S.; Aug. 7d. 02h., Saturn 4° N.; Aug. 20d. 21h., Jupiter 5° S.; Aug. 30d. 0h., Mars 2° S. Mercury is an evening star, setting about an hour before the sun on Aug. 1, but it draws closer to the sun and is in inferior conjunction on Aug. 31, and is not favourably placed for observation during most of the month. Venus sets about an hour after the sun on Aug. 1, but as the planet is approaching the sun it is not well placed for observation throughout the greater part of the month. Mars rises about 2h. 30m. during August and can be seen for some time before sunrise in the constellation Gemini. Jupiter rises at 22h., 21h. and 20h. on Aug. 1, 15 and 31, respectively, and is visible a little south of δ and ε Piscium throughout the month, stellar magnitude −2·3. Saturn, an evening star, sets about 1¾ hours after sunset on Aug. 1 but draws closer to the sun and is not easily seen at the end of the month, when it sets less than an hour after sunset. Occultations of stars brighter than magnitude 6 are as follows: Aug. 4d. 11h. 18m., α Leonis (*D*); Aug. 4d. 12h. 32·6m., α Leonis (*R*); Aug. 23d. 01h. 29·3m., μ Arie. (*R*). (*D*) and (*R*) refer to disappearance and reappearance, respectively, and the times refer to observations made at Greenwich. The Perseid meteors attain a maximum about Aug. 10–12, but moonlight will make observations of the shower somewhat difficult.

Announcements

THE honorary degree of LL.D. of the University of Aberdeen has been conferred on Sir William Ogg, director of Rothamsted Experimental Station, Harpenden, Herts.

HONORARY degrees of the University of Reading have been conferred on the following: *D.Litt.*, Sir John Beazley, professor of classical archæology in the University of Oxford, and Sir Frank Stenton, formerly vice-chancellor of the University of Reading; *D.Sc.*, Sir John Russell, formerly director of Rothamsted Experimental Station, and Sir Henry Tizard, chairman of the Advisory Council on Scientific Policy.

THE honorary degree of D.Sc. of the University of Wales has been conferred on Sir David Brunt, professor of meteorology in the Imperial College of Science and Technology, London.

THE following appointments have been made in the University of Leeds: Dr. R. P. Hullin, lecturer in biochemistry; Mr. W. S. Reith, research chemist and honorary lecturer in the Department of Botany.

POWER Jets (Research and Development), Ltd., have appointed Mr. G. C. R. Mathieson to be senior lecturer at the School of Gas Turbine Technology, Farnborough, Hampshire. Mr. Mathieson was until recently a senior scientific officer in the Aerodynamics Department of the National Gas Turbine Establishment, Pyestock, which he joined in 1946.

SIR ALEXANDER CARR-SAUNDERS has resigned from the chairmanship of the Colonial Social Science Research Council, owing to the pressure of other duties; he will be succeeded by Sir David Parry, professor of English law in the University of London since 1930. Sir Alexander has recently assumed the chairmanship of the Inter-University Council for Higher Education in the Colonies.

THE Annual Exhibition of the Amateur Entomologists' Society will be held on Saturday, September 22 (2 p.m. to 6 p.m.), at Buckingham Gate Central Schools, Wilfred Street, London, S.W.1. There will be exhibits of specimens, equipment, apparatus, photographs, etc., and talks by experts including Major Maxwell Knight. Further particulars can be obtained from the honorary publicity secretary of the Society, L. W. Siggs, 10 Repton Road, Orpington, Kent.

INTERNATIONAL CO-OPERATION IN THE ANALYSES OF THE DEEP-SEA CORES COLLECTED BY THE SWEDISH DEEP-SEA EXPEDITION 1947–48

By C. D. OVEY
British Museum (Natural History)

I RECENTLY had the good fortune to be the guest, for a few days, of Prof. Hans Pettersson, leader of the Swedish Deep-sea Expedition 1947–48, and several of his research workers in Sweden. It is evident that it will not be long now before many important results of the work on the Expedition's deep-sea cores, collected by Dr. B. Kullenberg with his piston core sampler, appear in print in that country. The chemical and biological analyses are being carried out with extreme care by a well-organized group of workers, partly at the Oceanografiska Institutet in Göteborg and partly in Stockholm, and at Grödinge where Mr. Gustav Arrhenius has a number working under his direction on cores from the Eastern Pacific.

The Oceanografiska Institutet is the 'home' of the investigations, whence the material is distributed. Both there, where mostly Central and Western Pacific and Indian Ocean material is being dealt with, and at Grödinge, the cores are carefully stored in cold air-proof rooms at a temperature of 5° C. in the presence of formalin. These precautions prevent shrinkage, cracking and drying, and ensure against bacterial action in the sediments which would cause oxidation of the manganese. Chemical tests are being carried out on the content of phosphorus, nitrogen, titanium, iron, nickel, vanadium, carbon and calcium carbonate. Tests of grain size are also being undertaken by Mr. Arrhenius. As with the single Atlantic core now being examined in the British Museum (Natural History) by my colleague, Dr. J. D. H. Wiseman, and I, it has been found by Mr. Arrhenius that the carbon dioxide content in Pacific cores is a reciprocal of the adsorbed water content. It is also agreed that a high percentage of carbon dioxide, which is derived from carbonate, is a reflexion of the productivity of the foraminifera which provided the material through the accumulated remains of their calcitic shells. Mr. Arrhenius has now given me a few samples from his Eastern Pacific cores, to discover whether warm-water foraminifera are abundant when the carbonate content is high in cores from that area, as has been shown to be true by the British Museum work on the Atlantic core already mentioned. It is hoped by co-operation of this sort to be able to link up the chemical work in Sweden, and its geological and hydrological implications, with the inferences of temperature changes of the surface layers of the ocean at present being made in Great Britain. It must be remembered that the results of the examination of the Pacific cores, shortly to be published, will cover a wide range of different hydrographic conditions through the comparison of a number of core-sections. The Pacific area samples, as shown by Dr. F. Koczy's work at Göteborg on the interpretation of echo-profiles and of the hydrographic properties near the floor in that area, indicate considerable vertical mixing due to the irregularity of the floor. From a study of the cores themselves, this is evidently as true of the past as it is of the present. The single Atlantic core being examined in Great Britain, however, suggests that deposition took place on the whole continuously and undisturbed, although there is some evidence of disturbance at a few depths due to bottom-living organisms. (I had the opportunity of examining part of the core at Göteborg and of seeing the log.) It therefore seems that the Atlantic core (No. 241 at 01° 10′ N., 19° 50′ W.), where the sedimentation was relatively undisturbed and the sea floor flat over a wide area, is ideal for the work on the interpretation of climatic change. The Pacific cores cannot be approached at this angle; but there is very good reason for supposing that, by application of the work done in Britain and the proof of the validity of planktonic foraminifera as temperature-indicators, temperature fluctuations will be traceable in the Pacific area.

One of the first of the Expedition's long cores was examined by Dr. F. B. Phleger, the first to apply foraminifera as temperature-indicators to this series. This core came from the Caribbean Sea, but it seems doubtful whether the local rate of sedimentation retained the constancy necessary for a close chronological problem. Nevertheless, Dr. Phleger has shown by his diagram that there were conspicuous and considerable variations in temperature in that area during the recent past.

As Prof. F. E. Zeuner ("Dating the Past", 2nd edit. 1950, p. 401) and Dr. J. D. H. Wiseman, in a recent address to the Society of Visiting Scientists, have implied, conclusions from single cores are tentative; but much will be learned as soon as Mr. Arrhenius publishes his work on the series of cores in the Eastern Pacific. Prof. Hans Pettersson was, however, very careful in his choice of core 241, which, although an isolated example, was obtained from a flat area of quiet undisturbed deposition. Further adjacent cores would naturally be of great value in establishing a standard for climatic variation in the equatorial Atlantic, but I wish to emphasize that it is my considered opinion and that of my colleague, Dr. Wiseman, that this particular core is singularly suitable for this purpose.

In Stockholm, Dr. R. W. Kolbe has been working with the diatoms of the Eastern Pacific cores and has provided Mr. Arrhenius with a fascinating story on the size distribution of *Coscinodiscus nodulifer* A. Schmidt. Dr. F. Brotzen is making a study of the benthonic foraminifera from cores in the same area. I was in complete agreement with him in the identity of the planktonic species which I am using as temperature-indicators. Interesting studies of radiolaria from Western Pacific cores by Mr. W. Riedel will be of great importance when linked with other work. His results, showing the presence of Tertiary forms, will be in print shortly.

Prof. Pettersson himself is conducting radioactive determinations on cores from the Central and Western Pacific Ocean, but this is a long and tedious operation. Carbon-14 tests, being made on the Eastern Pacific cores, will be of first-class importance; but unfortunately tests for this operation are done at the expense of considerable material, as it is necessary to use a large quantity for each count.

The above impressions are merely a very brief summary of the work now being carried out in Sweden on the material collected by the Swedish Deep-Sea Expedition, and in no way has space allowed for a complete survey. Let it be said that Prof. Pettersson has succeeded in building up a great network of scientific research on his cores both in Sweden, in north-west Europe, in Great Britain and in the United States. Every core, whether isolated or one of a group or sequence, is of value from some aspect of the deep-sea floor, which is so little known. It is not possible at this early stage to assess the worth of the work, whether geophysical, geochemical, biological or palæoclimatological. It is, however, evident even at this early stage that, whatever the aspect of approach, the whole will gradually be dovetailed into a preliminary story which will be a guide to future workers and explorers in this field in the same manner that the great *Challenger* Expedition of the last century became the foundation of oceanographical work to the present generation of marine investigators. We must therefore look forward with hope to co-ordinating this work further in August at the meeting of the Association d'Océanographie Physique in Brussels. It is essential to encourage co-operation in all the varied lines of study of the cores, because, however great the difficulties in obtaining sufficient financial assistance for this all-important work, collaboration, and not rivalry, is of prime importance; without it, what little money that is at present available would largely be wasted.

AN EXTRA-ADRENAL ACTION OF ADRENOTROPIC HORMONE

By Prof. HANS SELYE

Institute of Experimental Medicine and Surgery, University of Montreal

JUST fifteen years ago, I described in this journal the 'general-adaptation-syndrome' as the somatic expression of "the response to damage as such". It was surprising that all organs of the body show degenerative changes, with widespread pyknosis and catabolism, under the influence of various damaging agents; only the adrenal cortex exhibits signs of increased hormone secretion and cellular proliferation. This was ascribed to the increased production of 'adrenotropic hormone', now generally known as ACTH[1]. These observations lead us to the concept that non-specific damage, or 'stress', has its own physiology and pathology (quite apart from specific actions of the agent used to produce stress) and that the pituitary-adrenal system plays a cardinal part in this non-specific adaptive or defensive reaction[2,3].

Subsequent investigations showed that the acute thymus involution, which occurs during the first 'alarm-reaction' stage of the general-adaptation-syndrome, is prevented by suprarenalectomy, while active adrenocortical extracts can produce thymus involution, even in the adrenalectomized animal. Hence, I concluded that "the secretion of the adrenal gland must therefore be considered essential for the ability of the thymus to undergo sudden involution"[4]. Since after hypophysectomy stress causes neither adrenocortical stimulation nor thymus involution, it was thought that the thymolysis is elicited by stress through the discharge of adrenotropic hormone and the consequent increase in the production of corticoids[5].

The numerous pertinent reports, published during the intervening years, appeared to support this concept; indeed, it is now generally held that not only the thymolytic, but also all known actions of adrenotropic hormone are mediated through the hormones of the adrenal cortex, because adrenotropic hormone produces no obvious changes in adrenalectomized animals, or in patients with complete adrenal destruction[6].

Recent experiments revealed that many of the actions of somatotrophic hormone are likewise abolished by adrenalectomy and can be restored, even in adrenalectomized animals, by suitable treatment with corticoids (Selye, in the press). This raised the question whether some of the supposedly trans-adrenal actions of adrenotropic hormone might not also be direct, though dependent upon the simultaneous presence of corticoids in the body fluids. The results to be reported here show that such a peripheral synergism between adrenotropic hormone and corticoids does, in fact, exist. Concurrent treatment with adrenotropic hormone and cortisone caused pronounced thymolysis in the adrenalectomized rat, although each of these hormones given separately failed to do so at the same dose level.

Experimental procedure. Three experiments have been performed on a total of 120 female piebald rats. In each of these we used four groups of ten rats treated respectively as follows: (I) hypertensinogen: (II) adrenotropic hormone; (III) adrenotropic hormone and cortisone; (IV) hypertensinogen and cortisone. Hypertensinogen was administered merely in order to determine the possible effect of a non-hormonal foreign protein. It was given at a daily dose-level of 6 mgm., administered in the form of six subcutaneous injections of 1·0 mgm. in 0·1 ml. of saline, subcutaneously every four hours. Adrenotropic hormone (ACTH, Connaught Laboratories, Toronto, Lot No. 2–2, 3–1) was given at the same dose-level and in the same manner as the hypertensinogen. It will be recalled that in order to obtain maximal adrenocorticotrophic effects from adrenotropic hormone, it is essential to give it at short intervals; it is for this reason that injections were given every four hours during the day and night. Cortisone was administered in the form of one subcutaneous injection of 0·5 mgm. a day, in the form of a microcrystalline suspension (as distributed by Merck and Co., Ltd., Montreal) which contains 5 mgm. of cortisone acetate per ml.

All the experimental animals in the three series were bilaterally adrenalectomized and ovariectomized forty-eight hours before the initiation of the injections. Immediately after this, they were given 1 per cent sodium chloride instead of tap water as a drinking fluid. The removal of the gonads and adrenals was necessary in order to eliminate both the known endogenous sources of steroid hormones.

The three experimental series differed only in that injections were given in the first experiment during four days, in the second during six days, and in the third during nine days. At the end of each experiment the animals were killed by exsanguination and their thymus glands removed for weighing and histological study.

TABLE 1. EFFECT OF FOUR DAYS TREATMENT

Treatment		Hypertensinogen	ACTH	ACTH + cortisone	Hypertensinogen + cortisone
Body-weight (gm.)	Initial	121	121	121	121
	Final	117	109	114	120
Weight of thymus	in mgm.	366	319	203	282
	in mgm./100 gm. body-weight	308±18·5	294±16·1	179±15·9	237±18·1

TABLE 2. EFFECT OF SIX DAYS TREATMENT

Treatment		Hypertensinogen	ACTH	ACTH + cortisone	Hypertensinogen + cortisone
Body-weight (gm.)	Initial	108	108	108	107
	Final	109	104	104	109
Weight of thymus	in mgm.	299	291	161	249
	in mgm./100 gm. body-weight	275±23·5	280±21·8	156±13·7	228±17·4

TABLE 3. EFFECT OF NINE DAYS TREATMENT

Treatment		Hypertensinogen	ACTH	ACTH + cortisone	Hypertensinogen + cortisone
Body-weight (gm.)	Initial	110	110	110	109
	Final	129	108	118	131
Weight of thymus	in mgm.	423	303	168	283
	in mgm./100 gm. body-weight	324±18 1	280±15·6	141±16·4	217±12·6

Results. The details of the experimental arrangement, the initial and final body-weights, as well as the thymus weight expressed in mgm. and in mgm. per 100 gm. of body-weight (the latter with its standard error) are given in the accompanying tables.

It will be noted that none of the injected materials caused a significant loss of body-weight during our short-term experiments. Neither adrenotropic hormone nor an equivalent amount of non-hormonal protein (in the form of hypertensinogen) produced any consistent and significant involution of the thymus in these adrenalectomized rats. Cortisone, when given in conjunction with hypertensinogen, induced only a moderate degree of thymolysis. However, in all three series, marked involution of the thymus was noted in the animals given adrenotropic hormone and cortisone. Statistical analysis of the apparent differences between groups III and IV showed that in all three series the augmentation of cortisone thymolysis by adrenotropic hormone was significant. The value of P, in comparing the thymus weights in mgm. per 100 gm. between groups III and IV, was $< 0·05$ in group I, and $< 0·01$ in groups II and III.

Histological studies essentially confirmed the observations made by mere weighing of the thymus in that maximal thymolytic phenomena were noted in groups III of all three series.

Discussion. These data indicate that adrenotropic hormone can synergize the thymolytic effect of a corticoid hormone, such as cortisone, even in the absence of the adrenal cortex. It follows that the thymolytic effect of stressor agents is not necessarily due to increased production of corticoids through discharge of adrenotropic hormone, but that it may in part also result from a peripheral synergism between the hormone and the corticoids.

These findings call to mind certain observations made in this Institute by Dr. Herlant[6], who showed that the thymolytic effect of threshold doses of adrenocortical extract is increased by an alarm-reaction, even in adrenalectomized rats. The present observations suggest that this increase may have been due, at least in part, to an endogenous discharge of adrenotropic hormone by the pituitary of the animal exposed to stress.

It remains to be seen whether a disproportion between circulating adrenotropic hormone and corticoids can produce results qualitatively different from those normally elicited by either of these hormones, and whether conjoint treatment with the hormone and cortisone would be of special benefit in the treatment of those lymphatic, inflammatory and allergic diseases which respond favourably to glucocorticoids.

These investigations were supported by a grant from the National Cancer Institute of Canada. I am also indebted to Miss Marguerite Parent for technical assistance.

ANTITUBERCULOUS EFFECT OF CERTAIN SURFACE-ACTIVE POLYOXYETHYLENE ETHERS IN MICE

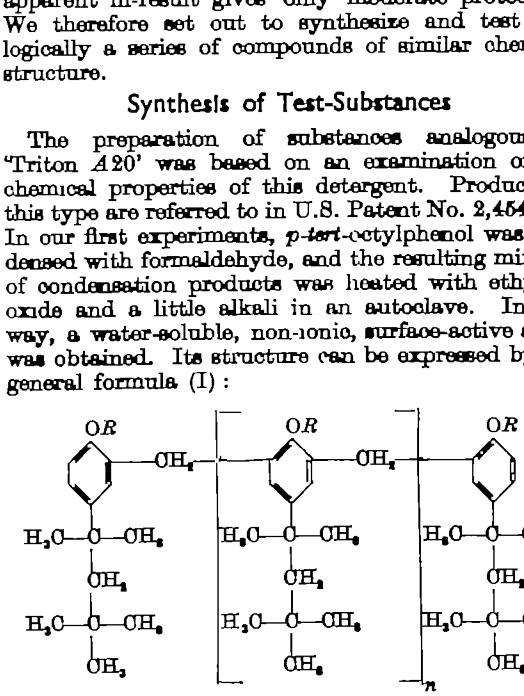
By Dr. J. W. CORNFORTH, Dr. P. D'ARCY HART, R. J. W. REES and J. A. STOCK

National Institute for Medical Research, Mill Hill, London, N.W.7

As part of a study, by two of us (P. D'A. H. and R. J. W. R.), of factors influencing the susceptibility of mice to experimental tuberculosis, methods of altering the body lipids were sought. For this purpose a new technique[1–4], by which the blood cholesterol and phospholipids could be maintained at high levels for several weeks by the repeated intravenous injection of the non-ionic surface-active agent 'Triton *A*20', was tried. This agent is described by its manufacturers (Rohm and Haas Co., Philadelphia; we are indebted to their associates, Charles Lennig and Co., Ltd., London, for supplies of the substance) as a 25 per cent aqueous solution of an arylalkyl polyether of phenol ('Triton *WR*1339'); and all doses of 'Triton *A*20' given below refer to this anhydrous material. In the first experiment, made more than a year ago, 'Triton *A*20' produced a striking suppressive effect on the course of a moderately acute tuberculous infection in mice. Further experiments amply confirmed this unexpected observation. 'Triton *A*20' has, however, undesirable toxic effects in mice. Injection of the optimal intravenous chemotherapeutic doses (15–25 mgm.) is followed immediately by convulsions, though these are transitory and seem to leave no after-effects; while a single injection of 25 mgm. intraperitoneally or 10 mgm. subcutaneously produces a gelatinous ascites or œdema, respectively, and the highest daily dose (2·5 mgm.) tolerated by these routes without apparent ill-result gives only moderate protection. We therefore set out to synthesize and test biologically a series of compounds of similar chemical structure.

Synthesis of Test-Substances

The preparation of substances analogous to 'Triton *A*20' was based on an examination of the chemical properties of this detergent. Products of this type are referred to in U.S. Patent No. 2,454,541. In our first experiments, *p*-*tert*-octylphenol was condensed with formaldehyde, and the resulting mixture of condensation products was heated with ethylene oxide and a little alkali in an autoclave. In this way, a water-soluble, non-ionic, surface-active agent was obtained. Its structure can be expressed by the general formula (I):



I

$R = -CH_2CH_2O(CH_2CH_2O)_{15-16}CH_2CH_2OH$ except where indicated otherwise.
$n = 0, 1, 2, 3$ and higher integers.

This product (*D*2) was found to be as active chemotherapeutically as 'Triton *A*20' (see below), and it was therefore decided to prepare products homogeneous with respect to *n*. Condensation of *p*-*tert*-octylphenol with ethylene oxide gave a toxic product (*D*3). 2 : 2′-Dihydroxy-5 : 5′-di-*tert*-octyldiphenylmethane (I; $n = 0$; $R = H$) was made from excess *p*-*tert*-octylphenol and formaldehyde by adapting a conventional method. Condensation of this crystalline substance with ethylene oxide afforded the product *D*4 (I; $n = 0$). *p*-*tert*-Octylphenol with formaldehyde and sodium hydroxide gave 2 : 6-*bis*hydroxymethyl-4-*tert*-octylphenol[4] and, contrary to an earlier statement[5], no difficulty was experienced in condensing this substance with excess *p*-*tert*-octylphenol to give 2 : 6-di(2′-hydroxy-5′-*tert*-octylbenzyl)-4-*tert*-octylphenol (I; $n = 1$; $R = H$) which, though non-crystalline, could be purified by distillation at a pressure of 10^{-2} to 10^{-3} mm. mercury. This compound was condensed with ethylene oxide to give *D*9*a* (I; $n = 1$).

Condensation of the substituted diphenyl methane (I; $n = 0$; $R = H$) with formaldehyde in glacial acetic acid saturated with hydrogen chloride (cf. refs. 5, 6), and subsequent molecular distillation of the reaction mixture after elimination of excess parent compound, gave a product consisting essentially of the tetracyclic compound (I; $n = 2$; $R = H$) which reacted with ethylene oxide to give *D*10*a* (I; $n = 2$). The residue in the molecular still was also condensed with ethylene oxide, giving *D*10*b* (I; $n = 4, 6, 8$, etc., together with unexpelled tetracyclic compound). For comparative biological tests, *D*10 (I; $n = 2, 4, 6$, etc.) was prepared from a resin obtained exactly as above except that molecular distillation was omitted.

In another experiment and as a possible alternative to molecular distillation, an attempt was made to purify the crude tetracyclic compound by successive countercurrent distribution between ligroin (boiling range 88°–101°) and 94 per cent aqueous ethanol at 0° C. Only a partial purification resulted, but the best fraction was condensed with ethylene oxide; the product (*D*11) showed activity similar to that of *D*10*a*.

The product isolated by a double molecular distillation of another batch of the crude tetracyclic compound was also shown by countercurrent distribution to be not quite homogeneous.

Finally, 2 : 6-*bis*hydroxymethyl-4-*tert*-octylphenol was condensed with excess of the substituted diphenyl methane (I; $n = 0$; $R = H$). A product, collected at 300°–310° in the molecular still, was presumably mainly the pentacyclic compound (I; $n = 3$; $R = H$). This gave *D*12 (I; $n = 3$) on condensation with ethylene oxide.

The results given below show that no activity can be observed in the products when *n* is less than 2. The presence of the di- and tri-cyclic compounds in mixtures such as *D*2 appears to have no advantage. On removing these substances as completely as possible by distillation from the resin corresponding to *D*2 and condensing the residue with ethylene oxide, the product (*D*2*a*; I; $n = 2, 3, 4$, etc.) was found to be as active as *D*2.

Bacteriostatic Tests

Paradoxically, in the light of the chemotherapeutic results to follow, 'Triton *A*20' was suggested[7] as a useful addition to fluid media for the culture of tubercle bacilli, since it promoted dispersed growth of virulent organisms (strain *H*37*Rv*); optimal concentrations were 0·1–0·01 per cent. and there was neither inhibition nor enhancement of growth in this range. We have confirmed the dispersive properties, but observed an increasingly bacteriostatic effect on strain *H*37*Rv* at concentrations greater than 0·1 per cent. Other workers[8] have reported an enhancing effect of 'Triton *A*20' on the growth of tubercle bacilli at lower, and an inhibitory action at higher, concentrations; the inhibitory range extended as the *p*H was increased. *D*3 did not permit growth of *H*37*Rv* at 0·01 per cent; our other products, whether active or inactive against infection with this strain in mice (see below), were less inhibitory to its growth *in vitro* than 'Triton *A*20', but were similarly dispersive. No bactericidal action on *H*37*Rv* by 'Triton *A*20' 0·1 per cent and 1·0 per cent at *p*H 6·8–6·6 was evident after 20 hours exposure.

Chemotherapeutic Tests

The chemotherapeutic assessment is illustrated by a typical experiment. Twenty-two female mice of the albino Parkes strain, weighing 18–20 gm., and fed on a stock mash diet, were infected intravenously with 0·06 mgm. dry weight (about 10^7 viable organisms) of *Mycobacterium tuberculosis*, strain *H*37*Rv*, grown in 'Tween 80'-albumin medium. Starting the next day, ten of the mice received intravenous injections of 25 mgm. of *D*2 in 0·2 ml. saline twice weekly for two weeks, the injections being given slowly; the other twelve mice served as an untreated control. The control mice lost weight, and nine of the twelve died with gross pulmonary tuberculosis between 18 and 26 days after infection (median survival time 23 days); one died of intercurrent infection on the fifth day; and the two remaining animals, which were sick, were killed on the thirty-fourth day and their lungs showed well-marked tuberculous lesions. In contrast, apart from one death from intercurrent infection also on the fifth day, none of the ten treated mice died; they gained weight and appeared healthy when they were killed on the thirty-fourth day, that is, twenty-three days after the last injection; and they had air-containing lungs showing in eight of them scattered tuberculous lesions, pin-point in size, and varying in number, and in the ninth animal somewhat more advanced changes.

Using the same test, the following preparations, at the doses stated, had a similar order of anti-tuberculous activity to *D*2: 'Triton *A*20' (15–25 mgm.), *D*2*a* (25 mgm.), *D*10 (25 mgm.), *D*10*a* (15 mgm.), *D*10*b* (25 mgm.), *D*11 (15 mgm.) and *D*12 (25 mgm.). On the other hand, given at the following maximum tolerated doses, *D*4 (5 mgm.) and *D*9*a* (7·5 mgm.) were inactive. When the twice-weekly intravenous dose of 'Triton *A*20' was reduced to 10, 5 and 1 mgm., none of the three series of animals showed deaths from tuberculosis during the experiment, but the pulmonary lesions on killing were increasingly severe. The results obtained were as effective when the course of treatment with 'Triton *A*20' (25 mgm.) was started five days as one day after infection, and even a single dose at five days profoundly reduced the mortality and the lung lesions. Moreover, although individual animals failed to receive one or more doses after the first, in the usual course of four, owing to difficulties in repeatedly injecting the tail vein, this seemed to make little or no difference to the therapeutic results. When the usual course of 'Triton *A*20' (15 mgm.) was started ten days after infection, no protection was evident. Streptomycin, 2,000 units daily subcutaneously, gave results similar to 'Triton *A*20', 15 mgm. and 5 mgm. twice weekly intravenously, both drugs being started on the day after infection and administered for two weeks. When, however, the type of experiment was varied by killing about eight (instead of three) weeks after cessation of treatment, most of the streptomycin-treated mice had died of chronic pulmonary tuberculosis, whereas the animals treated with 'Triton *A*20' (15 mgm.) were still alive though their lungs showed that the infection had progressed. An experiment in which 2·5 mgm. of 'Triton *A*20' was given daily subcutaneously for two weeks, from the day after infection, resulted in similar protection against death to that given by 15 mgm. twice weekly intravenously, but the pulmonary lesions on killing (34 days) were more advanced in the majority of the animals.

Pharmacology and Toxic Effects

We have confirmed the observation[1-3,9] that intravenous injection of 'Triton *A*20' is followed by a rise in blood cholesterol, associated, when the rise is considerable, with milky serum. Estimations made two days after the end of a two weeks course of twice-weekly injections of 25 mgm. in mice showed a four- or five-fold increase in blood cholesterol, with milky serum, the levels returning to normal in about a week; with doses of 10 mgm. and 5 mgm. there was a two-fold and no increase, respectively. Blood cholesterol estimations were not made after giving our own products, but milky serum was observed at 24–48 hr. after a single intravenous injection of 15–25 mgm. of all that could be given at these doses, except *D*12. Similar hyperlipæmia was produced by the higher doses given by the intraperitoneal and subcutaneous routes. The adrenal glands from mice given a course of 'Triton *A*20' intravenously (15–25 mgm.) were pale pink, instead of the characteristic yellow. Histochemical tests showed the cortex to have been stripped of fat and cholesterol, these being apparently restored to normal in one or two weeks after cessation of treatment, the cholesterol more slowly than the fat. Sections of liver showed some decrease of fat, but the fat depots in general appeared unaffected. A similar temporary pallor of the adrenals was noted after one or more intravenous injections of most of our products, and subcutaneous and intraperitoneal administration with the larger doses also produced this phenomenon.

All the surface-active agents mentioned here have an ultra-violet absorption peak at 278 mμ, and this characteristic was used to estimate 'Triton *A*20' and *D*2 in the blood, after precipitation of the blood proteins by a 4 : 1 ethanol–ether mixture. The blood concentrations reached after single intravenous injections of 25 mgm. of 'Triton *A*20' were high, and their fall remarkably slow. The concentrations per ml. were 7 mgm. at 24 hr., 3 mgm. at two days, 2 mgm. at three days, and 0·8 mgm. even at four days. A course of *D*2 25 mgm. daily subcutaneously for ten days gave, four days later, 4 mgm. per ml. On the other hand, no 'Triton *A*20' was detectable in the blood after 100 mgm. had been given daily orally for a month.

*D*3 was the most toxic of the series to mice, its intravenous LD_{50} being 3 mgm. and death being immediate. For *D*4 and *D*9*a* the LD_{50} was 12·5 mgm. by this route. All but one of the other products were tolerated intravenously at doses varying from 15 mgm. to 75 mgm. without convulsions, in contrast to 'Triton *A*20', and without other serious symptoms; *D*12, however, was associated with transitory spasticity. Since *D*2 contained both *D*4 and *D*9*a* in proportions such as would have been expected to confer an appreciable toxicity, it would seem that admixture with the higher polymers had masked this. Further evidence of this phenomenon is provided by the comparative hæmolytic tests. None of our products tested intraperitoneally or subcutaneously at single 20–25 mgm. doses (*D*2, *D*2*a*, *D*10 and *D*12) gave rise to ascites or subcutaneous œdema, nor did *D*2*a*, *D*10 or *D*12 do so after seven to ten daily subcutaneous injections of these amounts. A more detailed examination was made on animals killed nine days after they had completed a course of 25 mgm. of *D*2 intravenously twice weekly for three weeks. They seemed healthy and had gained weight. At autopsy the principal organs were normal in appearance and size (except for the adrenals already described), and adipose tissue was normally distributed. Microscopically also, these organs showed no abnormalities; in particular, the liver cells showed no obvious degenerative changes, in contrast to the livers of animals treated with 'Triton *A*20', which often had small areas of focal necrosis. The livers appeared normal also in mice that had received courses of *D*2*a*, *D*10, *D*10*a* and *D*10*b* intravenously, but damage was seen in a small proportion after *D*11 and *D*12. We have not observed the presence in excessive quantities of 'foam cells' in the reticulo-endothelial systems of our animals, as described by Payne and Duff[10].

Serial No.	Chemical structure	Inhibitory concentration* (gm./100 ml.)	Chemotherapeutic activity	Intravenous toxicity		Hæmolytic ratio ('Triton $A20$' = 1)
				LD_{50} in mgm.† (single injection)	Liver damage (course of injections of 15–25 mgm.)	
$D2$	I; n = 0, 1, 2, 3, etc.	1·0	+	>75·0	0	0·02
$D2a$	I; n = 2, 3, 4, etc.	1·0	+	>62·5	0	0·02
$D3$	p-Octylphenol polyoxyethylene ether	0·01	Too toxic for test	3·0		1,600
$D4$	I; n = 0	1·0	0	12·5		500
$D9a$	I; n = 1	>1·0	0	12·5	± (7·5 mgm.)	1·0
$D10$	I; n = 2, 4, 6, etc.	>1·0	+	>50·0	0	0·25
$D10a$	I; n = 2 (substantially)	>1·0	+	>50·0	0	0·25
$D10b$	I; n = 4, 6, etc (and unexpelled I; n = 2)	>0·5	+	>25·0	0	0·25
$D11$	I; n = 2 (substantially)	>1·0	+	>25·0	±	
$D12$	I; n = 3 (substantially)		+	>50·0	±	
'Triton $A20$'		0·7	+	>25·0	±	1·0

* No growth at two weeks in synthetic medium containing 2·5 mgm. albumin and 0·0008 mgm. (moist weight) tubercle bacilli per ml.
† Mice weighed 18–20 gm. each.

'Triton $A20$' had a low hæmolytic activity *in vitro*, this finding being in agreement with other workers[11]. Tests with our products in comparison with this agent showed that $D3$ was 1,600, and $D4$ 500, times as hæmolytic, while $D9a$ had the same activity. The other products showed somewhat lower hæmolytic activities than 'Triton $A20$', particularly $D2$ and $D2a$, which gave values of one-fiftieth or less. Mouse serum was never seen to be pigmented even after the largest doses of 'Triton $A20$', or of any of the products that showed equal or lower hæmolytic activity *in vitro*. Capillary permeability tests with intravenous pontamine blue revealed a contrast between $D4$, which markedly increased leakage of the dye through the vessels into the tissues, and 'Triton $A20$', $D2$ and $D2a$, which showed no such effect.

Discussion

Within the limits of the present study, the products tend to be less toxic, and more active against tuberculous infection, as molecular size increases. Antituberculous activity in compounds of formula I may perhaps be limited to a definite range of values of n: it is worth noting that an increase of one unit in n raises the molecular weight by about 1,000.

Marked bacteriostatic activity *in vitro* was found only with the simplest compound ($D3$), which was too toxic to be tested chemotherapeutically. All our other products, both active and inactive *in vivo*, showed an approximately equal bacteriostatic power of a low order. It remains doubtful, therefore, whether direct bacteriostatic action is responsible for the antituberculous effect in mice, in spite of the high concentrations attainable in their blood. The relevance of the remarkable hyperlipæmia, and loss of lipids from the adrenal glands, to chemotherapeutic effectiveness is also doubtful, since 'Triton $A20$' was definitely antituberculous at doses too small to produce these phenomena, while they were not apparent even after the higher, and effective, doses of $D12$.

The detoxifying action of the higher polymers on the toxic lower members of the series, as well as their persistence in the blood, suggests the possibility of using these compounds in association with other, even toxic, drugs having high tuberculostatic activity *in vitro*.

Experiments are in progress with a method of reverse phase partition chromatography with the object of isolating the pure compounds containing four and more phenolic nuclei in the molecule. The substituents in the phenolic nuclei will also be varied. On the biological side, the reactions of the tissue white cells to these surface-active substances, and any possible antituberculous effect in animal species other than mice, will be investigated.

Some of this work is forming the subject of a patent application.

We are indebted to Dr. A. J. P. Martin for his advice in connexion with the partition chromatography.

Summary

The development of experimental tuberculosis in mice is markedly inhibited by injection of certain non-ionic, water-soluble, surface-active preparations of low toxicity, having the general formula I ($n > 1$), obtained by reaction of ethylene oxide with condensation products of formaldehyde with p-*tert*-octylphenol. Some of the more important results relating to these products are summarized in the accompanying table.

RADIOCHEMICAL TECHNIQUES IN ANALYSIS

IN conventional radioactive tracer methodology a labelled substance is added to a system so that its physical or chemical fate in the system can be followed by its radioactivity. In this way radiochemical techniques have been more used as a research tool than as an aid to routine chemical analysis. There are several ways, however, in which radiochemical techniques may be effectively used in analytical chemistry, some of which were exemplified at the recent meeting organized by the Physical Methods Group of the Society of Public Analysts and Other Analytical Chemists. The meeting, under the chairmanship of B. S. Cooper, was held in the rooms of the Institute of Physics in London on

May 22. This 'radiochemistry meeting', which was the second to be held under that title, was well attended and very successful, and promises to become a useful annual event.

Four papers were presented at the meeting. The first, by F. P. W. Winteringham, A. Harrison and R. G. Bridges (Pest Infestation Laboratory), was read by the first author and described the application of radiochemical techniques to quantitative paper-chromatographic analysis. Radiochemical techniques have been so applied in three ways: (1) the mixture for analysis already contained labelled components as in tracer experiments, or it was exposed to a labelled reagent before chromatographic separation so that one or more of the components were converted into radioactive derivatives; (2) the finished paper chromatogram was exposed to a labelled reagent which combined selectively with one or more of the separated components, the excess of reagent then being removed, leaving a radioactive isotope either associated or combined with the components; (3) the finished paper chromatogram was irradiated in the Harwell Pile so that any components containing an element of suitable activation cross-section was made conspicuously radioactive. In all cases the labelled chromatograms were scanned radiometrically so that the labelled components could be located or estimated. A simple device was described in which uni-dimensional paper chromatograms or strips cut from a two-dimensional chromatogram were fed automatically at a controlled rate through a slot so that consecutive sections of the paper were exposed for a given time interval to a screened end-window Geiger–Muller tube under conditions of uniform geometry. By using a suitable integrating circuit connected to a pen-recording milliammeter or self-balancing potentiometer, the mean rate of count was plotted against the distance along the strip, giving the required radio-chromatogram. The effects of β-particle self-absorption by the paper, and its variation, have been calculated to be small and unlikely to impair quantitative work even with soft β-emitters like carbon-14 or sulphur-35. Several radiochromatograms, obtained by the methods discussed, were presented.

The second paper, by E. Lester Smith and D. Allison (Glaxo Laboratories), dealt with the paper chromatographic analysis of penicillin mixtures labelled with radioactive sulphur-35. Dr. Lester Smith described how crystalline penicillins containing up to 600 microcuries of sulphur-35 per mgm. were prepared biosynthetically in a medium containing sodium sulphate labelled with sulphur-35. A point of interest was that the mould *P. chrysogenum*, *Q*176, tolerated up to one curie of sulphur-35 per litre of medium. The penicillin mixture was resolved on a buffered paper chromatogram by the method of Goodall and Levi. The separated components were located or estimated by three methods and the results compared. In the first method (Goodall and Levi) the developed chromatogram was placed against an agar plate inoculated with *B. subtilis* so that on incubation the separated penicillins were located and estimated by the zones of bacterial inhibition. In the second method the strips were placed against X-ray film in the dark so that the components labelled with sulphur-35 could be located autoradiographically. Finally, the paper chromatogram was cut up into equal sections which were mounted below a thin end-window Geiger–Müller tube and the β-activity of the sulphur-35 assayed radiometrically. The results by all three methods agreed well, and the experiments demonstrated clearly the value of a radioactive tracer technique in checking existing chemical and biological methods of assay. An interesting outcome of these experiments was that a significant fraction of the penicillins appeared to be destroyed after application to the paper strip, this being suggested by a zone of radioactivity at the origin not associated with antibiotic activity.

A. A. Smales read the third paper, contributed by himself and B. D. Pate (Harwell), and described a method for the ultra-micro determination of arsenic by neutron activation. Pile irradiation of a sample containing arsenic gives rise to radioactive arsenic-76 by means of the reaction $^{75}\mathrm{As}(n,\gamma)^{76}\mathrm{As}$. Arsenic-76 decays by β-emission of maximum energy 3·0 MeV. with a half-life of 27 hr. Radiation due to this isotope in a chemically separated fraction is characterized by its energy and decay period. The sensitivity and accuracy of the method were tested by a carrier technique in which a known excess of inactive arsenic was added to the irradiated sample and a known proportion isolated by conventional analytical techniques, the activity of arsenic-76 in the separated fraction then representing a known proportion of the arsenic originally present in the sample. Close agreement was obtained between chemical and activation analysis at high concentrations, and the results obtained by the activation method alone were consistent on samples diluted well beyond the limits of chemical detection. The data provide an excellent example of the sensitivity and accuracy of the methods of activation analysis. The determination of as little as 10^{-4} μgm. of arsenic in biological samples appears to be quite practicable. Their great sensitivity, notwithstanding the methods, are not without pitfalls for the unwary. This was illustrated in the application of the method to the assay of germanium dioxide for arsenic. On neutron activation, germanium itself gives rise to more than one radioactive isotope of arsenic—for example, by the sequence, $^{74}\mathrm{Ge}(n,\gamma)^{75}\mathrm{Ge} \xrightarrow{\beta} {}^{75}\mathrm{As}(n,\gamma)^{76}\mathrm{As}$, so that 'spurious' arsenic appears as a result of the irradiation. Arsenic-77, which also arises from germanium, may be distinguished radiometrically. Mr. Smales suggested that a similar difficulty might arise during the irradiation of samples rich in bromine or selenium, for example, by the reaction $^{79}\mathrm{Br}(n,\alpha)^{76}\mathrm{As}$.

The last paper was presented by R. D. Keynes (Cambridge), who described the application of the methods of activation analysis to the determination of sodium and potassium in biological samples. Samples for analysis were irradiated in the Harwell Pile together with samples of spectroscopically pure sodium carbonate and potassium bicarbonate which were used as reference standards. It was found that, during the irradiation of desiccated nerve fibres isolated from cuttle-fish, sodium-24, potassium-42, phosphorus-32 and sulphur-35 were the principal radionuclides formed, the last no doubt partly arising from the reaction $^{35}\mathrm{Cl}(n,p)^{35}\mathrm{S}$. Sodium-24 and potassium-42 arise by neutron activation of the natural isotopes, so that the corresponding radioactivities are a direct measure of the sodium and potassium originally present. By a simple screening technique the sodium-24 and potassium-42 were distinguished by their energetic γ- and β-emission respectively, and chemical carrier separation was unnecessary. A small correction had to be made for the phosphorus-32, which could be determined after the short-lived sodium and potassium isotopes had decayed to insignificance. A modification in estimating the potassium only was to add a known excess of potassium carbonate carrier to the irradiated sample and, precipitating a known fraction of the total potassium as the dipicrylaminate, this salt was then radiometrically assayed separately. These methods have been used successfully on a routine basis for the determination of weights of the order of 0·5 μgm. of sodium and 5 μgm. of potassium in biological samples. The results indicate that as little as 0·05 μgm. of sodium can be estimated to within a few per cent, so that the potentialities of the method in chemical analysis are obvious.

It would not be appropriate to record here more than a few points raised in the ensuing discussion. R. C. Chirnside asked if the decomposition of the penicillins noted during the paper chromatography of the labelled material minimizes the value of the Goodall and Levi method; Dr. Lester Smith replied that, unless the relative decomposition of the individual penicillins was unequal, the value of the original method would not be affected because it was used to show the proportional composition of the penicillin mixture rather than the individual weights. J. Haslam asked if the method of radioactivation analysis can be applied to the determination of iodine in sea water, to which Mr. Smales replied that the relatively short half-life of the iodine-128 produced by neutron activation of natural iodine makes the determination very difficult, since any separation and counting would have to be completed within a matter of two or three hours of removing the sample from the pile; however, Mr. Smales mentioned that the determination of a range of trace elements in water by radioactivation analysis is, in fact, being investigated. A. C. Mason wondered if the methods could be used for the determination of boron in plant material—a difficult problem in chemical analysis—and Mr. Smales replied that boron unfortunately gives rise to no suitable isotope on neutron irradiation. Other items discussed ranged from the particular advantages to be expected as a result of combining radioactive tracer techniques with paper chromatography to the use of radioactivation analysis for the detection of arsenic in poisoned victims.

F. P. W. Winteringham

UNIVERSITY OF GLASGOW

FIFTH CENTENARY CELEBRATIONS

On the evening of June 29, the last of a series of 'At Homes' in the Bute Hall at the University brought the celebrations of the fifth centenary of the University of Glasgow to a close. They began almost a fortnight before with the arrival on June 17 and 18 of nearly two hundred delegates representing universities and other learned bodies in all parts of the world, and of many other distinguished scholars invited to receive honorary degrees.

On the afternoon of Monday, June 18, the guests were welcomed informally at faculty receptions in the College Rooms and Queen Margaret Union, and renewed or established friendships which were strengthened by the academic and social functions of the ensuing days. That evening many guests attended the first McEwen Memorial Concert in the Hunter Hall.

On Tuesday, June 19, a very full programme began with the presentation of addresses in the Bute Hall, when delegates, representatives and graduands from at home and abroad were welcomed by the Chancellor, Lord Boyd-Orr. Before a full assemblage of the Senatus, academic staff and honorary doctors of the University, the guests bringing messages of greeting were called in turn and handed their greetings to the Chancellor. More than two hundred such messages were presented, all graciously worded and many of them beautifully illustrated. They have been on display to the public, together with many other addresses received by post, in the Upper Library throughout the period of the celebrations, and have attracted many visitors.

One of the most colourful and impressive ceremonies took place on the Tuesday afternoon when, in robed processions, delegates, graduands and the Chancellor, Court and Senate of the University went in bright sunshine from the Royal Infirmary to the Commemoration Service in Glasgow Cathedral, the first home of the University congregations five hundred years ago. The whole of the Cathedral quire was filled with the academic gathering, while wives and friends occupied the nave, an assemblage in all of some 1,200. The sermon was preached by the Minister of Glasgow, and others officiating were the Principal, the Professor of Divinity, the Clerk of the Senate, the Moderator of the General Assembly of the Church of Scotland and the University Chaplain. The music was played by the Professor of Music.

On Tuesday evening some eight hundred guests were entertained to dinner in two gatherings, one at the Central Hotel presided over by the Chancellor, and the other at the adjacent Grosvenor Restaurant where the chairman was the Rector. It was a happy circumstance that the Prime Minister, who was to receive the next day the honorary degree of Doctor of Laws, and Mrs. Attlee arrived in time to be present. Among the speakers were the Lord Justice General, the President of the University of California, the Lord Bishop of Durham, Sir Oliver Franks, the Principal of McGill University, Prof. F. L. Ganshof, of the University of Ghent, Prof. J. M. Holst, of the University of Oslo, and Prof. M. Le Breton, of the University of Paris.

The mornings of June 20 and 21 were reserved for the two major academic functions, the honorary graduation ceremony and the commemoration oration by Lord Macmillan of Aberfeldy respectively. For these functions some 2,700 persons assembled on each occasion in St. Andrew's Hall, almost half of them in academic robes. The colourful splendour on each occasion was perhaps unprecedented in the history of the University or of the city.

At the graduation ceremony twelve honorary degrees of Doctor of Divinity and fifty-four of Doctor of Laws were conferred. Among those receiving the degree of LL.D. were the following: Prof. E. D. Adrian, professor of physiology in the University of Cambridge; Prof. A. C. Aitken, professor of mathematics in the University of Edinburgh; The Right Hon. C. R. Attlee, Prime Minister; Sir John Beazley, professor of archæology in the University of Oxford; Prof. Niels Bohr, professor of theoretical physics in the University of Copenhagen; Sir John Cockcroft, director of the Atomic Energy Research Establishment, Harwell; Sir John Craig, steelmaker in Glasgow; Dr. H. W. Dodds, president of Princeton University; Dr. R. Dohrn, director of the Zoological Station at Naples; Dr. P. J. Du Toit, president of the South African Council for Scientific and Industrial Research; Prof. T. G. Halle, professor of palæobotany in the University of Stockholm; Prof. B. A. Houssay, formerly professor of physiology in the University of Buenos Aires; Prof. F. H. Knight, professor of social sciences in the University of Chicago; Prof. H. R. Kruyt, formerly professor of physical chemistry in the University of Utrecht; Prof. E. O. Lawrence, professor of physics in the University of California; N. A. MacR. MacKenzie, president of the University of British Columbia; Sir Arcot Mudaliar, vice-chancellor of the University of Madras; Prof. J. Ortega y Gasset, formerly professor of philosophy in the University of Madrid; Lord Reith of Stonehaven; Prof. D. S. Russell, professor of pathology in the University of London; Prof. L. S. Ruzicka, professor of organic chemistry in the Swiss Federal Institute of Technology; Prof. René Sand, professor of social medicine in the University of Brussels; Prof. G. G. Simpson, professor of vertebrate palæontology in Columbia University; Prof. Norman Kemp Smith, formerly professor of logic and metaphysics in the University of Edinburgh; Prof. J. G. Solch, professor of geography in the University of Vienna; Sir Richard Southwell, formerly rector of the Imperial College of Science and Technology, University of London; Prof. S. Timoshenko, professor of mechanics in Stanford University; Prof. O. Veblen, formerly professor of mathematics in the Institute for Advanced Study at Princeton; Prof. C. E. Weatherburn, professor of mathematics in the University of Western Australia; and Prof. G. H. Whipple, professor of pathology in the University of Rochester. The speakers on behalf of the new graduates were the Bishop of Strängnäs, Lord Reith, the president of Princeton University and the president of the University of British Columbia. The new and past doctors and their wives were afterwards entertained to luncheon in the Bute Hall by the Chancellor, Court and Senate, when replies to the toast of "The New Graduates" were made by Prof. C. H. Dodd, of Cambridge, and Prof. L. S. Ruzicka, of the Swiss Federal Institute of Technology.

The Wednesday programme was completed by two happy social functions at which Town and Gown mingled, an afternoon reception at the Trades House by the Deacon-Convener of the Trades of Glasgow and the Collector of the Trades House, and a reception in the evening at the City Chambers by the Lord Provost and Magistrates.

At the opening of the Oration Ceremony on June 12, the Chancellor expressed the regret of all that Their Majesties the King and Queen were unable to grace the gathering with their presence, and the Principal read an address from the University to the King and a gracious message from His Majesty. Lord Macmillan then delivered the Commemoration Oration, an eloquent tribute to the past achievements of the University and expression of the ideals which should guide its future. The conclusion of this ceremony, the last of the academic functions of the celebrations, was most fittingly the maiden speech of the Prime Minister as a doctor of the University of Glasgow. More than two thousand guests attended a reception at the University on the Thursday afternoon. In the evening, while their wives were the guests of Lady Hetherington at an 'at home' in the College Rooms, the delegates and new graduates were entertained to dinner by the Senate in the Grosvenor Restaurant. Robes and formalities were laid aside. The Principal presided and the speakers at the dinner included the Vice-Chancellors of the Universities of Cambridge and London, Dr. H. R. Kruyt of the Universities of Utrecht and Amsterdam, and Dr. B. Blanshard of Yale University.

On June 22, a precedent was followed that had been created fifty years before (almost to the day) on the occasion of the ninth jubilee, when the University took its guests for a cruise on the Firth of Clyde. As in 1901, it was a day of midsummer sunshine and the Firth a panorama of mellow beauty. The *Queen Mary II* sailed in the morning with eight hundred guests from Bridge Wharf in the centre of the city past the shipyards and Dumbarton Rock and cruised in the Kyles of Bute, Loch Striven and Loch Riddon, returning round the Cumbraes to Wemyss Bay, whence the journey to Glasgow in the evening was made by train. On the morning of June 23, some 150 guests who still remained were taken by coach to Loch Lomond.

The following week was reserved for gatherings of Glasgow's own graduates, and more than three thousand members of the General Council and their wives were entertained in the Bute Hall on June 26, 27, 28 and 29. J. B. NEILSON

AMERICAN PHYSICAL SOCIETY

ANNUAL MEETING

THE 1951 annual meeting of the American Physical Society was held at Columbia University, New York City, during February 1–3. The annual meeting of the American Association of Physics Teachers took place simultaneously at Barnard College. At the joint session of the two bodies on February 2, the retiring presidential address of the Physical Society was delivered by Prof. I. I. Rabi, who took as his subject "Molecular Beam Researches in Nuclear and Electronic Physics"; the Oersted Medal of the Association was presented to Prof. J. W. Hornbeck (who died on February 27); and the tenth Richtmyer Memorial Lecture was delivered by Prof. J. C. Slater, who spoke on "The Electron Theory of Metals". The after-dinner speaker at the banquet in the evening was Prof. J. R. Oppenheimer, who spoke principally about meson theory.

At the business meeting of the Physical Society the following officers were elected: *President*, C. C. Lauritsen; *Vice-President*, J. H. Van Vleck; *Secretary*, K. K. Darrow; *Treasurer*, G. B. Pegram; *Managing Editor*, S. A. Goudsmit. The headquarters of the *Physical Review* have now been removed from the University of Minnesota, which housed them for the past quarter of a century, to the Brookhaven National Laboratory.

Twenty-eight invited papers, in addition to two hundred and ninety-one (a new record) ten-minute papers, were contributed to the meeting of the Physical Society. The invited papers included: a group of papers describing the Brookhaven National Laboratory and the research work carried on there; various papers on nuclear physics, including one by C. C. Lauritsen on the work on nuclear energy-levels at the California Institute of Technology; four papers mainly concerned with mesons; in the division of electron physics, J. A. Hornbeck on a review of positive-ion mobilities in the noble gases; in the division of fluid dynamics, E. Teller on magneto-hydrodynamics and G. Birkhoff on some modern problems in classical hydrodynamics; J. Bardeen on supraconductivity and lattice vibrations, and two contributions by English visitors, S. Chapman on some phenomena of the upper atmosphere and M. H. L. Pryce on nuclear hyperfine structure of paramagnetic resonance. A complete list of the papers, together with abstracts, is given in the minutes of the meeting, which are printed in the April 15 issue of the *Physical Review* (82, 291; 1951).

It was reported that the membership was 9,740, and that the income of the Society had exceeded expenditure by a substantial amount, but that there was little hope that the Society would be equally fortunate during 1951. A change in the by-laws was approved which empowered the Council to fix the erms on which members of the Society shall receive either *Physics Abstracts* or *Engineering Abstracts*. The subscription prices at which these journals are sold to the Society by the Institution of Electrical Engineers, London, have recently been raised, and he purpose of the amended by-law is to enable the Council to recover the extra cost. A committee was appointed to make recommendations about the future relations of the Society and *Science Abstracts*.

The minutes include a copy of the letter sent by Dr. D. W. Bronk, president of the National Research Council, on December 11, 1950, to R. L. Clark, the director of the Manpower Office of the National Security Resources Board, in which specific recommendations with regard to the question of scientific man-power in the United States of America, the setting up of a National Scientific Personnel Board and the establishment of a register of professionally qualified scientific workers are outlined. The Council of the Physical Society formally approved of these recommendations.

MOVEMENT OF SWIFTS IN SUMMER

THE year 1950 was a good one for studying the movements of swifts (*Apus apus*), and during the year the movements of forty thousand birds were recorded: a report on the observations has been made by H. G. Hurrell and recently described in *British Birds* (**44**, No. 5; May 1951).

Movements were found to take place not only during arrival and departure but also in the middle of the breeding season as well. The date when movement occurs is the main reason for classifying it as immigration, emigration or a movement occurring between the two. There is no certain way of distinguishing movements in the field, although there is a tendency for larger numbers of birds to group together when they are leaving Great Britain.

Swifts appear to penetrate the country from the south and work northwards. Arrivals over many years average a day or two earlier in the south than in the south-east. The east coast as a rule is reached rather late and usually in such small numbers that there is little to indicate any spring passage of swifts from the British Isles to other countries.

It is difficult to say when the arrival period ends because movements which have a migratory appearance may take place at any time while swifts are in Britain. Large movements occur in June and early July. These are thought to be undertaken because unfavourable weather forces the swift to seek regions with more adequate food supplies; the food of the swift is adversely affected by the passage of a cyclone or depression.

In 1947 Koskimies suggested that the birds tried to avoid an advancing depression by flying against the wind round the south-east side of it, and that these weather movements are undertaken by first-year non-breeding swifts and, to a varying extent, by the breeding birds. If mid-season movements were always bad-weather movements, a comparison of the data with meteorological records should show some kind of broad correlation. At times this could be found; but there are cases when there is no obvious connexion between major movements and low temperatures or low pressures. The 1950 mid-breeding season records took place at a time when weather conditions were comparatively stable and an anticyclone was maintaining fine warm weather over most of the British Isles. Nor is there clear evidence that the birds taking part in these weather movements are first-year non-breeding swifts. As yet the evidence is insufficient to say whether large mid-season movements are composed mainly of British swifts or of swifts which have just arrived from overseas.

It is impossible to say when emigration begins, since it commences during July when mid-season movements may still be taking place. Many breeding and most non-breeding swifts leave during July. During this month in 1950 swifts were frequently on the move, while August showed an almost complete absence of any swifts flying northwards; the main directions were south or south-west. Early in August the British Isles are practically drained of breeding swifts. Yet quite large numbers were recorded throughout the month at favoured spots, especially on the east coast. During the last ten days of August, there was a widespread and, for the time of the year, remarkably strong wave. Such large numbers on these late dates are surprising, and it is suspected that these are largely swifts from other countries in more northerly latitudes visiting Britain on their return passage.

In another article in the same issue of *British Birds* ("The Use of Mobile Observers in the Study of Patterns of Migration"), Arnold Darlington criticizes much of the work on the migration of swifts which has been done in recent years because observations have been made at fixed vantage points, a method which has inherent in it several possible errors.

These errors are reduced if watchers deploy over an area and attempt to locate the main concentrations of swifts and to follow up any flight-lines radiating from them. The use of mobile squads of observers operating on bicycles has proved particularly useful, skilled riders being able to ride at a speed greater than the ground-speed of a migrant swift. In May 1950 the use of fifty-seven cyclists experienced in this mobile method of observation and operating in nineteen units enabled an intensive study to be made of the distribution of migrating swifts passing through south Cambridgeshire. From their results it would appear that, first, in anticyclonic, stable conditions, with light wind and mild temperatures, the movement of swifts tends to follow individual tracks and, although flight-lanes may be followed to some extent, they are not immediately apparent and may require careful seeking. The swifts tend, however, to be attracted by certain places, and here the flight-lanes may become concentrated and obvious, often persisting in their essential form for days on end. Second, in more unsettled conditions, with strong wind, low temperatures and cloud, the swifts may take to watercourses in great numbers, flying low and tending to 'pile up' in some places.

Ancient Greek Plated Coins

The techniques of the production of the officially issued plated coins of ancient Greece have been discussed at length by Campbell[1]. In the samples examined, it was inferred that the plating had normally been effected by a fusion process analogous to that by which Sheffield plate was later made. Examples are, however, reported in which a silver solder may have been employed, though the evidence is not sufficiently clear, in Campbell's view, to provide definite proof.

During the examination of a number of similar plated coins, one, however, a didrachm of Neapolis, B.M.C., p. 100/59, the date of which is approximately 300 B.C., was found in which it was certain that solder had been used. Between the core which, incidentally, consisted of copper 95·7 per cent, lead 0·7 per cent, zinc 0·4 per cent and silver 1·9 per cent, and the silver case, there existed a definite, and, on the surfaces, regular layer of a silver–copper alloy. At the edges of the specimen, however, as is shown in Fig. 1, two layers of this solder are to be seen. In Fig. 2 is shown the structure of this duplex layer at higher magnification. It consists, essentially, of a silver–copper alloy, which, from the structure, would appear to be approximately 60 per cent silver–40 per cent copper. It will also be noted from Fig. 2 that the eutectic structure which would be expected if it were due merely to interdiffusion of silver and copper at high temperature is almost non-existent, as a result presumably of previous spheroidization.

From these observations, coupled with the examination of the whole section of the coin, it is apparent that the plating operation was effected by first making a shallow silver cup to fit the copper core, lining this with a thin sheet of the silver solder, and, after the insertion of the core, covering the whole with another inverted cup, similarly lined with solder. When the whole was afterwards reheated above the temperature of the silver–copper eutectic, the solder would melt and run between the two cups, fusing core and plate together. A gentle hammering of the rim would complete the preparation of the blank, which, as the twinned structure of both core and plate shows, was then struck hot. This plating process i shown diagrammatically in Fig. 4. Fig. 1 woulc then represent a section such as that on *XX*. Suc a method of production is in excellent agreemen with that suggested by Prof. E. Darmstaedter[2].

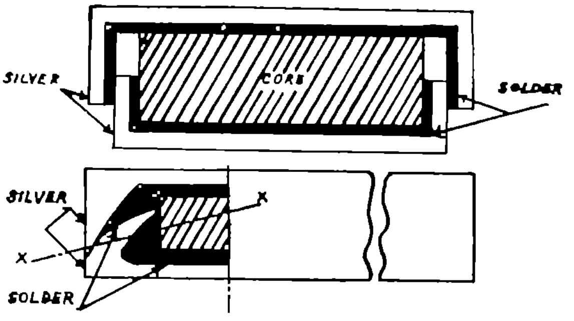

Fig. 4

For comparison, in Fig. 3 is shown the typica silver–copper eutectic obtained by direct fusion, ir all ways similar to the corresponding structure observed by Campbell. This proof of a definit soldering operation at this early date seemed o: sufficient interest to justify publication.

We are pleased to acknowledge financial assistanc from Messrs. Imperial Chemical Industries, Ltd., ir support of this and other work on the methods o production of ancient coins.

X-Ray Crystallographic Measurements on some Compounds showing Intramolecular Overcrowding

It has been recognized for some time that there exist classes of aromatic structures in which the (intramolecular) distance of closest approach between non-bonded atoms, calculated on the basis of conventional bond-lengths and bond-angles, is smaller than the sum of the van der Waals' radii of these atoms. Bell and Waring[1] have suggested the term

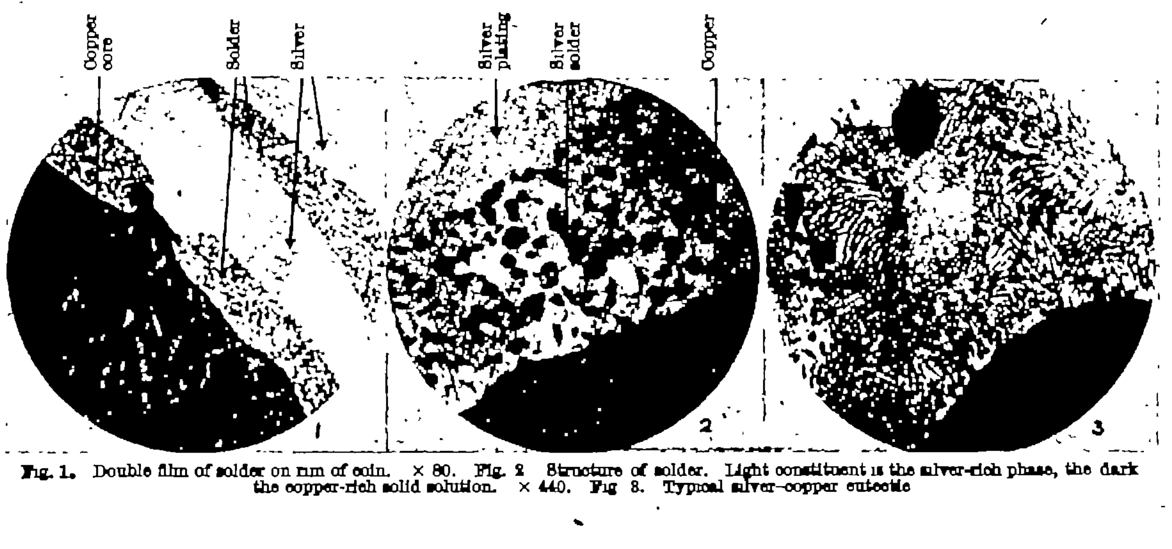

Fig. 1. Double film of solder on rim of coin. × 80. Fig. 2 Structure of solder. Light constituent is the silver-rich phase, the dark the copper-rich solid solution. × 440. Fig 3. Typical silver–copper eutectic

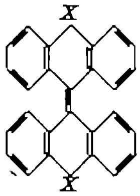
intramolecular overcrowding' for this type of steric effect.

We may assume that the strain due to such abnormal approach distances is relieved by distortion of the molecule: indeed, substituted 3 : 4-benzphenanthrenes[2] and 3 : 4 : 5 : 6-dibenzphenanthrenes[1] have been fully or partially resolved into optical somers, and are not, therefore, planar molecules. Such departure from the regular structure of the aromatic ring system can be investigated by X-ray crystallographic methods; we have therefore surveyed a series of compounds, of which the most promising are listed in Table 1. We are now investigating tetrabenznaphthalene[3] and 3 : 4-benzphenanthrene[4] by two-dimensional Fourier methods; discussion of their 'abnormalities' must await completion of the structure analysis.



There exists a second class of overcrowded molecules of the accompanying general formula, such as dianthrone (X = CO) and dixanthylene (X = O), in which the steric effect depends on the presence of the central double bond (the corresponding dihydro compounds, such as 10 : 10′-dianthronyl, are free from overcrowding). These compounds are also of interest because of their thermochromic properties (for example, ref. 5), which have recently been investigated[6,7] spectroscopically; as a result of these studies, dianthrone has been assigned a configuration in which "the ground state is a singlet with the double bond in a state of considerable torsion"[6].

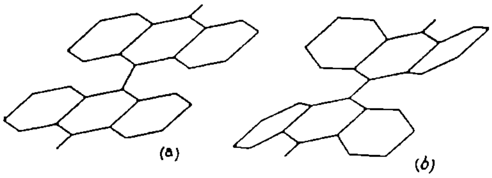


Fig. 2

Our preliminary results for dianthrone and dixanthylene are given in Table 2. Cell dimensions and space group of dianthrone unequivocally imply that the molecule has a centre of symmetry. In dixanthylene it is not possible to determine the space group unambiguously from the systematic absences alone; however, the Wilson test[8,9] applied to the intensity distribution in the $h0l$ and $hk0$ zones has shown both zones to be centric (see Fig. 1). We therefore assign to dixanthylene the space group $C2/c$. Packing considerations make it unlikely that the molecule has a twofold axis of symmetry. We conclude that dixanthylene, like dianthrone, is centrosymmetric.

We can envisage the following three extreme possibilities for their molecular shape: (i) fully planar; (ii) biplanar (Fig. 2a); (iii) bent (Fig. 2b). In both the biplanar and the bent forms the overcrowding is relieved. In order to decide between these possibilities, we are now investigating the crystal structure of dianthrone by two-dimensional Fourier methods.

If the molecular configuration of dianthrone in the crystalline state is retained in solution, the X-ray evidence conclusively rules out any configuration in which the two anthrone ring systems are twisted

Fourier Synthesis by Optical Interference

The expression of the electron density in a crystal as a Fourier series is the mathematical equivalent of the process of image formation by light waves in an optical instrument. Thus, if the X-ray diffraction data can be converted into appropriate light waves, it should be possible to produce an image of a crystal optically instead of by the more arduous process of calculation. Making use of this idea, Bragg[1] produced an image of the projection of the crystal diopside, CaMg(SiO$_3$)$_2$, on the (010) plane.

This crystal, however, provides only a special case, in that no phase differences exist between the scattered waves. Buerger[2] has solved the problem of introducing phase differences by the use of mica plates, tilted to produce the required retardation. Marcasite, FeS$_2$, the crystal to which he has applied the method, is centrosymmetrical, and so the phase differences in the scattered beams are either 0 or π; thus mica plates need be placed only in certain of the interfering beams, and only a fixed tilt is required.

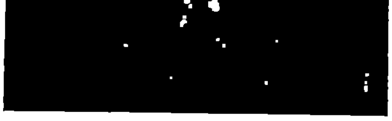

Fig. 1. Optical synthesis of durene

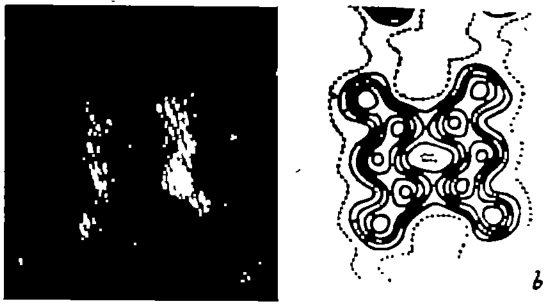

Fig. 2(a). One molecule from Fig. 1 enlarged
Fig. 2(b). Electron density map for comparison with Fig. 2(a)

We have made use of another method whic although it can be used only for centrosymmetric crystals, appears to us to be simpler and more easil adaptable to experimentation. An opaque plate i drilled with equal holes at the points of the reciproca lattice section of the crystal; in each hole is place a small tube fitted with a disk punched from a optically uniform sheet of mica, and the whole i viewed through crossed nicols. Each mica plat transmits an intensity of light depending upon it orientation, and thus each may be turned to transmi an intensity proportional to the intensity of th corresponding X-ray reflexion. It may easily b shown that the amplitude of the transmitted ligh is proportional to $\sin 2\varphi$, where φ is the angular dis placement of a disk from one of its extinctio positions; thus, on passing through $\varphi = 0$ th amplitude changes sign, and in this way phas changes of π can be simulated.

We have applied the method to the data given b Robertson[3] for durene, and the result, together wit the calculated electron-density map for comparison is shown in Figs. 1 and 2. Although the representatio is not perfect, the molecule is quite recognizable, an the method would certainly serve to distinguis between possible and impossible combinations o signs.

A more complete account of the method, togethe with plans for obtaining a clearer image, and fo making use of it in crystal-structure determination will be published elsewhere.

Cold Emission of Electrons in Spark Gaps

Studies[1,2] of sparks in short gaps have show that under suitable conditions breakdown can occu within times, after the application of the gap voltage which are considerably smaller than those expecte if the initial ionization in the gap were due only t natural processes such as natural radioactivity, cosmi rays, or the break-up of gaseous ions. It is clear therefore, that there must be another source o initiatory electrons. There is, however, considerabl doubt concerning the nature of these sources, an the mechanism of electron liberation from them.

Pre-breakdown electron production in a spark gap is related to the time-lag of sparking, and considerable information on electron production can be obtained from analysis of time-lag data; under certain conditions, the inverse of the statistical lag is a measure of the rate of electron emission from the cathode under the given gap conditions. In this way, the rates of electron emission from cold nickel and tungsten electrodes, in short parallel-plate gaps in the atmosphere, under the influence of spark overvoltages up to 200 per cent, have been investigated in this laboratory, using a technique which permitted the effect of a single initial electron to be recorded. The spark current was suitably limited so that effects such as electrode erosion were negligible. The investigation showed that the surface condition and previous treatment of the cathode exerted great influence on the rate of pre-breakdown electron emission. A most significant result was that enhanced cold emission occurred when the average electric field F ($= V/d$) in the gap was of the order of 10^5 volts/cm., and it is not easy to see how electron emission of the magnitudes observed could be field emission from a metal, as it is well known that such emission requires fields of 10^7 volts/cm. or more.

In order to investigate this problem, the rate of electron emission i from the cathode was measured for various values of gap voltage V, and a relationship between i and V was found. For a cathode of nickel, oxidized by previous sparking in air, considerable electron emission of the order of 10^4 electrons per second was found for values of the macroscopic electric field in the gap of the order of 10^5 volts/cm. The relationship between i and V experimentally established was:

$$\ln(r) = -A/V + B, \qquad (1)$$

where $r = id^2/V^2$.

The following interpretation of this equation indicates that the mechanism of emission of these initiatory electrons was a field process.

The Fowler–Nordheim[3] field emission equation can be written:

$$\ln(i/F^2) = -(6{\cdot}8 \times 10^7 \varphi^{3/2})/F + \ln(CS),$$

where S is the area of the emitting surface, and $C = 38{\cdot}8 \times 10^{12} (\mu)^{1/2}/(\mu + \varphi)\, \varphi^{1/2}$, in which φ is the work function of the surface, and μ is the parameter of metallic electron distribution in the Fermi–Dirac statistics.

This equation can be written:

$$\ln(r) = -(6{\cdot}8 \times 10^7 \varphi^{3/2} d)/V + \ln(CS). \qquad (2)$$

Thus, equations (1) and (2) are the same when $A = 6{\cdot}8 \times 10^7 \varphi^{3/2} d$, giving the same slope in the $\ln(r)$, $1/V$ curves; and $B = \ln(CS)$, giving the same intercept on the $\ln(r)$ axis.

Thus, the experimental equation (1) leads to estimates of φ, the work function of the source from which the electrons were extracted, and also of S the area of the emitting surface. Values thus obtained are $\varphi \doteq 0{\cdot}1$ volt, and $S \sim 10^{-14}$ cm.^{2}.

If the value of $\varphi \sim 4{\cdot}5$ volts for common metals is used in equation (1), then to obtain the measured emission of 10^4 electrons per second, F must be of the order of 10^7 volts/cm.

In this work, F, given by V/d, is of the order of 10^5 volts/cm. Consequently, we have alternative conclusions to draw; either F in these experiments at the surface of the electrodes is some hundreds of times greater than the macroscopic applied field, and the electrons are released from the pure metal, or φ, the effective work function of the surface layer, is much less than 4·5 volts, and the electrons are released from that surface.

Schottky[4] has estimated a maximum value of about 10 for the intensification of the local field at microscopic points on the electrode surface, and substitution of this value in equation (1) gives $\varphi = 0{\cdot}48$ volt.

On this view, then, the electrons could not have come from a pure metal, still less from a metal with an electronegative monomolecular oxide surface film with a still higher effective work function. The most reasonable suggestion is that the electrons come from the surface oxide layer itself, and these estimated values of φ and of the emitting area of approximately molecular cross-section suggest oxygen ions as the source. These results, therefore, support the view that the cathode oxide layer, always present on electrode surfaces in air, is the source of electrons, extracted by field emission, which can initiate impulse sparks.

Ultra-Violet Absorption Spectra of Gallium and Indium Monofluorides

RECENT work on equilibria involving aluminium monohalides[1] suggested that gaseous gallium and indium monofluorides might be formed by reaction of the metals with aluminium trifluoride. This has proved to be so, and we have been able to photograph the absorption spectrum of gallium fluoride at about 1,000° C., and that of indium fluoride at about 1,400° C.

Vibrational analyses of the three band systems for each molecule expected by analogy with the other halides[2] have been completed. The constants derived are given in the accompanying table.

State			ν_e	ω_e	$x_e\omega_e$	$y_e\omega_e$
GaF	C	$^1\Pi$	47364·$_6$	541·$_9$	8·$_8$	−0·6
	B	$^3\Pi_1$	33427·$_7$	666·$_4$	4·$_3$	—
	A	$^3\Pi_0$	33098	659·$_4$	4·$_0$	—
	X	$^1\Sigma+$	0	623·$_1$	3·$_4$	—
InF	C	$^1\Pi$	42808·$_8$	463·$_6$	7·4$_9$	−0·4$_6$
	B	$^3\Pi_1$	31257·$_7$	572·$_6$	3·4$_8$	—
	A	$^3\Pi_0$	30442	571·$_2$	3·4$_5$	—
	X	$^1\Sigma+$	0	534·$_7$	2·5$_6$	—

The assignment of states A and B as $^3\Pi_0$ and $^3\Pi_1$ respectively is supported by the fact that the bands of the systems A—X are single-headed, whereas those in B—X possess two heads. The $^1\Pi$ states converge rapidly to give dissociation limits at about 6·3 eV. for gallium fluoride and 5·7 eV. for indium fluoride. A more detailed account of these systems will be published later.

Theoretical Determination of Electron Density in Organic Molecules

In a recent paper, Abrahams, Robertson and White[1] have determined the electron density in naphthalene by means of X-ray analysis. They found that the electron density is greatest at the carbon atom in the meso-position, smallest at the β-position, and intermediate at the α-position. Between each pair of carbon atoms there is an electron density, evidently due to the binding pairs, which assumes its largest value between the α- and β-positions, and the smallest value between the two meso-positions.

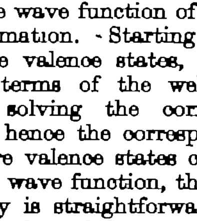
It may be of interest to note that precisely these results can be derived, at least qualitatively, from the theory of the chemical bond. I have used the method first applied by Heitler and Rumer[2] for determining the wave function of naphthalene in the zeroth approximation. Starting from a set of independent pure valence states, the energy can be calculated in terms of the well-known exchange integrals (by solving the corresponding secular equation), and hence the corresponding linear combination of pure valence states can be obtained.

Knowing the wave function, the calculation of the electron density is straightforward and follows the same pattern as that of the energy. If u_a, u_b are the wave functions of the valence electron in the atoms a and b, then the electron density depends on two types of integral:

$$\int |u_a(1)|^2 d\tau, \qquad \int u_a^*(1)\, u_b^*(2)\, u_a(2)\, u_b(1)\, d\tau. \quad (1)$$

Each occurs with certain algebraic coefficients arising from the solution of the secular problem. The first integral in (1) gives rise to an electron density at a, the second also to an *exchange density* between a and b. Values for these integrals can be estimated from the analogy of the hydrogen molecule, but the qualitative results depend on the valence structure of the molecule alone.

Carrying out this analysis, and taking into account only the interaction between neighbouring atoms, the following results are found. We denote the atoms in naphthalene as in the accompanying formula,



the electron density in a by ρ_a, the density between a and b by ρ_{ab}, etc. Then

$$\rho_k > \rho_a > \rho_b, \quad \rho_{ab} > \rho_{bc} > \rho_{ak} > \rho_{kl}.$$

All exchange densities ρ_{nm} are smaller than the ρ_n. The results are qualitatively in perfect agreement with the above experiments.

Attempts in a similar direction have been made by Daudel and Pullman[3]; but their results are not quite consistent because they depend on the choice of the independent basis of valence diagrams. This is not the case in our method.

Details will be published in the *Helvetica Chimica Acta*. I wish to thank Prof. W. Heitler for his advice and guidance, and the Stiftung fur Stipendien auf dem Gebiete der Chemie for a grant.

Ferromagnetic Resonance Absorption and a New Transition in NiOFe$_2$O$_3$ at Low Temperature

Microwave absorption phenomena, similar t those reported by Bickford for magnetite[1], have bee observed for nickel ferrite in measurements at wave-length of 3·2 cm. made from room temperatur down to − 195° C. At the lowest temperature two absorption peaks were obtained at 1,490 Oe. an 200 Oe., the latter gradually decreasing with risin temperature and finally disappearing at abou − 120° C. The value of g and the maximum absorption increase with decreasing temperature. A anomaly in the magnetization, similar to that foun by Weiss and Forrer for magnetite[2], was observe in the range − 120° to − 195° C., where the magnetization falls suddenly by an amount which is th smaller, the higher the field. Similarly, the electrica resistivity rises suddenly in the same range. Thes phenomena may be due to a transition betwee − 120° and − 195° C.

Experiments at temperatures below − 195° C. ar being planned.

I wish to express my thanks to Dr. T. Muto of th University of Tokyo for his valuable suggestions, an also to Mrs. Y. Torizuka, J. Simoizaka, Y. Kojim and Miss K. Takahasi for their assistance during th course of the experiments. Detailed results of th present work will be published in *Sci. Rep. RI.T.U.*

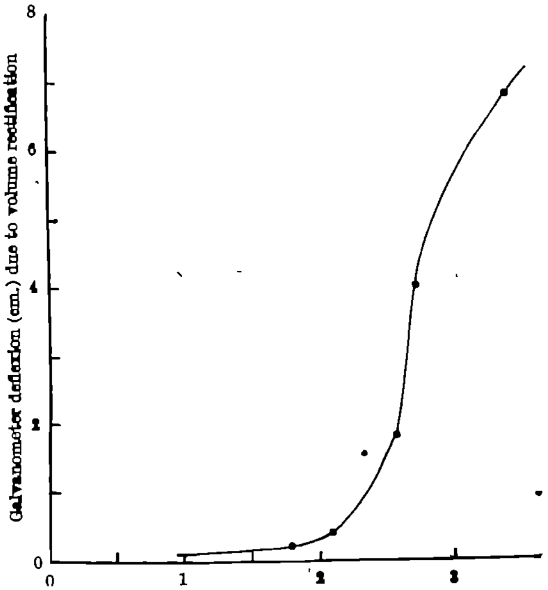
Volume Rectification in Zincite

The experiments of Khastgir and Das Gupta showed that when carborundum, zincite or silico was placed between two mercury electrodes givin large contact areas, there was considerable rectification, while similar experiments with symmetrica crystals like iron pyrites, magnetite, galena, etc showed no rectification when the surface effects wer eliminated. These experimental results suggeste that the rectification observed in polar crystals such as carborundum, zincite or silicon with electrodes o large contact-areas should be associated with th asymmetry in the structure of these crystals. The experiments of Deaglio[2] with two different thicknesses of carborundum having the same contact-areas on the opposite faces, mechanically scraped plane and platinized, showed that rectification per centimetre thickness, as indicated by the static characteristic curves, was the same. This proved that the observed rectification in carborundum was definitely associated with the volume of the crystal and not with the area in contact with the electrodes. The object of the present communication is to report some experimental results with zincite, which has shown similar rectification depending on the volume of the crystal. A theoretical treatment is also given of the origin of volume rectification in polar crystals.

The zincite crystal cut in the form of a cube was mounted between two plane electrodes of large contact area pressed tightly against the opposite faces. Having applied a constant radio-frequency voltage om a tuned circuit to the electrodes, the rectified urrent was measured by a suitably shunted mirror alvanometer for various thicknesses of the same rystal, keeping the resistance of the circuit constant. 'he two opposite faces of the same area were care-illy scraped to reduce the thickness and, after mount-ig the crystal, the total resistance of the crystal ircuit was made the same by inserting additional esistance to make up for each reduced thickness. 'he observed rectified current in the crystal circuit as found to decrease with the decrease of thickness or the same input radio-frequency voltage. The xperimental results for a frequency in the neighbour-ood of 1 Mc./s. are shown in the accompanying raph.



Curve for zincite, 0·945 Mc./s.

In explaining the experimental results, we shall ssume that the specific resistance of a polar crystal or the two opposite directions has different values, ρ_1 and ρ_2. If t be the thickness and A the area of he crystal in contact with either electrode, then the ectified current is:

$$i_r = V\left[\frac{1}{r_1} - \frac{1}{r_1 + (\rho_2 - \rho_1)\,t/A}\right], \qquad (1)$$

where r_1 is resistance of the crystal circuit in one irection, V the applied voltage and ρ_2 is assumed o be greater than ρ_1. Putting $m = (\rho_2 - \rho_1)/r_1.A$, we get:

$$i_r = \frac{V}{r_1} \cdot \frac{mt}{1 + mt}. \qquad (2)$$

Introducing now the 'electro-resistive' effect of Osterberg[3] in crystals like carborundum and zincite which have no centres of symmetry, the resistance of such a polar crystal, under isothermal conditions, long any direction, can be expressed as a function of the applied voltage, as follows:

$$r = a + bV + cV^2, \qquad (3)$$

where a, b, c are electro-resistive constants. The lifference in resistance for currents flowing in the two opposite directions is then given by

$$r_2 - r_1 = (\rho_2 - \rho_1)\,t/A = 2b.V;$$

so that

$$V = m.r_1.t/2b. \qquad (4)$$

Substituting this expression for V in (2), we get

$$i_r = \beta.t^2/(1 + mt), \qquad (5)$$

where

$$\beta = m^2/2b.$$

For carborundum and zincite crystals, either of which has a very high resistance, $m \ll 1$, and we should expect a square-law variation of rectified current with thickness, when the total resistance of the crystal circuit is kept constant. From our experimental results with zincite, it appears that Osterberg's 'electro-resistive' effect, which is the basis of formula (5), is the main cause of volume rectification observed in such a polar crystal.

Crustal Layers of the Earth

In a discussion on the granitic layer of the earth's crust[1] Dr. P. L. Willmore criticized the P^* data from near earthquakes and is reported to have remarked that, "In South Africa, a similar tendency for waves to arrive early at distances beyond 120 km. is associated with the exposure of high-velocity rock in the region where the onsets are observed". This brief statement with regard to the South African observations may be misleading.

In a seismic study of the crustal layers in the western Transvaal[2], it was found that between 220 and 300 km. there was a large and well-defined phase which was rather more than 1 second early with respect to the P_1 line ($V_1 = 6{\cdot}09$ km./sec.). It was pointed out that the early onsets could be explained in three ways: (1) on the basis of a single-layer crust with a thin surface covering of high-velocity material in the neighbourhood of the field stations; (2) on the basis of a single-layer crust in which the velocity increases with depth; (3) on the basis of an intermediate layer.

If (1) be the correct explanation, then either (*a*) the phase travelled in the faster medium for its *entire* path after leaving the Witwatersrand system, or (*b*) it must have entered the surface layer of higher velocity from the lower-velocity material. In case (*a*), the travel-time graph should have been a straight line with a slope corresponding to the higher velocity. In (*b*), it is well known that it is only with exceptional dispositions of a high-velocity over a low-velocity medium that a phase with relatively large amplitudes would be observed. The geological maps of the area do not suggest that such dispositions of the media exist in the area in question.

Correspondingly early S arrivals were not observed. This fact, far from weakening the case for a change in the composition of the crustal layers at depth, serves to strengthen it. Assuming a single-layer crust with P and S velocities of $V_1 = 6{\cdot}09$ km./sec. and

$v_1 = 3{\cdot}68$ km./sec., the thicknesses of the crustal layer as calculated from the P and S observations are $34{\cdot}2 \pm 0{\cdot}8$ and $38{\cdot}2 \pm 1{\cdot}0$ km. respectively. The inference to be drawn from the smaller thickness found for the P phases is that the ratio of the average velocities of P and S waves in the crust is greater than the ratio V_1/v_1. This is consistent with the fact that early P arrivals were observed between 220 and 300 km., whereas early S arrivals could not be identified with certainty.

Finally, there is a third argument. Given the thicknesses and velocities in the layers, it is possible to calculate the distances at which the P and S phases totally reflected at the Mohorovicic Discontinuity should appear. For the single-layer crust, these distances are 72 and 87 km. for P and S respectively. For the two-layer crust the corresponding figures are 92·9 and 99·5 km. respectively. The observations agree satisfactorily with the predictions for the two-layer crust.

Any one of the above arguments taken by itself might not be regarded as convincing; but when they are considered together it would seem reasonable to conclude from the South African observations that there is a change in the composition of the crustal layers at depth, and that the change is such that the ratio of the P and S velocities increases at depth. It is not possible to decide between a continuous variation of composition and a discontinuous change, that is, the existence of an intermediate layer.

It is of interest to examine the implications of this change in the ratio of the velocities. Birch and Bancroft[3] noted that "Quartz is peculiar in possessing high rigidity with respect to its bulk modulus". It follows that for rocks containing a fair proportion of quartz it would be expected that the ratio of the P and S velocities would be low. This tendency is strikingly illustrated by the data given in the accompanying table.

VELOCITIES OF CERTAIN ROCKS AT 4,000 kg./cm.² AND 30° C.

Rock	Percentage of quartz	V_P (km./sec.)	V_S (km./sec.)	$\frac{V_P}{V_S}$
Sandstone (quartzitic)	80	6·08	4·00	1·52
Granite, Quincy	25	6·08	3·61	1·68
Granite, Rockport	28	6·24	3·59	1·74
Syenite, Ontario	0	6·05	3·36	1·80
Norite, Sudbury	8	6·49	3·65	1·78
Diabase, Vinal Haven	0	6·97	3·88	1·80
Diabase, Maryland	0	6·96	3·83	1·82
Gabbro, Mellen	0	6·96	3·71	1·88
Gabbro, French Creek	0	7·15	3·98	1·80

(The table was compiled from Table 5–8, p. 80, of the "Handbook of Physical Constants", Special Paper 36 of the Geological Society of America, and papers by Birch and his associates.)

Thus the seismic observations in South Africa are consistent with the view that the crustal layers increase in basicity with depth.

[1] *Nature*, 166, 1053 (1950).

[2] Willmore, Hales and Gane, *Bull. Seis. Soc. Amer.* (in the press).

[3] Birch and Bancroft, *J. Geol.*, 48, 752 (1940).

MUCH of the evidence produced by Prof. A. L. Hales is directed against the postulate of uniformity for the materials above the Mohorovicic Discontinuity. The conclusions are indisputable up to that point and the only question is the extent to which differen types of rock are collected into horizontal strat extending over continental distances.

The observations can be explained on the assumption that two materials exist in the crust, propagatin P waves with velocities of about 6·09 and 6·8 km./sec respectively. The reflexions from the Mohorovici Discontinuity show that substantial volumes of th high-velocity material must exist within 100 km. o the origin, whereas the fast refracted wave is observe between 220 and 300 km. At the shorter distances the high-velocity material must be deeply buried but there is no direct seismological evidence concerning the depth of the material which produces th refracted wave. The discrepancy between the estimates for the thickness of a single upper layer confirm the heterogeneity of the crust without yielding any further evidence on the distribution of the materials

Seismologists often postulate horizontal stratification because they feel that such a distribution i inherently plausible, when their data may be equally consistent with other structures. The Transvaa seismograms show only that appropriate materials exist at an appropriate depth in one location, and a undetermined depths elsewhere. In some areas such evidence might be sufficient; but in the Transvaa the more distant recording stations were resting o the diabasic lavas of the Ventersdorp series, the properties of which are very similar to those required for the high-velocity material. Hence, the advocates of a high-velocity layer at depth have to admit three layers in the western Transvaal, but they dismiss the uppermost one as being too thin to transmit waves of measurable amplitude. In fact, the thickness o the lavas is known to exceed 5,000 ft. in some areas[1] but I have not seen any figures relating to the thickness under the seismic stations. The difficulty o getting seismic energy into the surface layer does not appear to be overwhelming. The matter could be decided if observations along other profiles were available or possibly by a more exhaustive examination of existing data. In the meantime, it seems premature to assert that horizontal stratification provides the only possible explanation of the results.

Reaction of Metmyoglobin with Hydrogen Peroxide

THE formation of a well-defined red complex between hydrogen peroxide and methæmoglobin or metmyoglobin is well established[1–3]. Keilin and Hartree found that the formation requires one molecule of peroxide per hæmatin iron atom. With reducing agents this complex is reduced back to methæmoglobin or metmyoglobin, and in the overall reaction the peroxide is *reduced* to water.

In this respect the complex is very different from that formed between ionic ferric iron and hydrogen peroxide, which Evans, George and Uri[4] showed to have the ion-pair structure

$$[\mathrm{Fe}.^{3+}.\mathrm{O_2H}^-], \text{ that is, } \mathrm{Fe.O_2H}^{2+}.$$

In a kinetic investigation of this system, Barb, Baxendale, George and Hargrave[5] found evidence that this complex plays no independent kinetic part, and that peroxide decomposition is initiated by electron transfer as follows:

$$Fe^{3+} + O_2H^- \rightarrow Fe^{2+} + HO_2, \qquad (1)$$

which results in the partial *oxidation* of the peroxide by the ferric ion. This difference in the fate of the peroxide in the two systems prompted our present investigation using recrystallized horse metmyoglobin, the preliminary results of which are outlined below.

The formation of a metmyoglobin – peroxide complex was observed at all hydrogen ion concentrations between *p*H 5·5 and 12·0. However, the reaction is only straightforward in the *p*H range 8–9, where maximum formation of the complex is obtained and complete regeneration of the metmyoglobin can be effected by adding mild reducing agents. The spectrum of the complex in this region shows a sharp band at 549 mμ with $\varepsilon_{mM} = 9{\cdot}8$ and a broad band appearing as a shoulder at 570–585 mμ with $\varepsilon_{mM} = 8{\cdot}4$. In the Soret region there is a sharp band at 423 mμ with $\varepsilon_{mM} = 107$. With solutions of *p*H < 8 some complex is formed, but an additional reaction involving the hæmatin also occurs and full recovery of the metmyoglobin is not observed. When the reaction is carried out in solutions of increasing alkalinity above *p*H 9·0, progressively less complex is formed and a hæmatin degradation product, colourless both in the visible and Soret regions of the spectrum, is produced.

Table 1. FERROCYANIDE REDUCTION OF THE COMPLEX AT *p*H 8·0

Initial complex × 10⁵ *M*	Ferrocyanide × 10⁵ *M*	Observed complex left × 10⁵ *M*	Complex reduced × 10⁵ *M*	Ratio : $\frac{Fe(CN)_6^{4-}}{\text{complex}}$
2 4	1·0	1·4	1·0	1·00
2·4	1·5	1·0	1·4	1·07
2·4	2·4	0·1	2·3	1·04
4 0	3·0	0·9	3·1	0 97

In addition to ascorbic acid, hydroquinone, and *p*-phenylene diamine, the complex was found to oxidize cysteine, *l*-malachite green, iodide ion (but not bromide ion) and ferrocyanide ion. This last reducing agent proved satisfactory in spectrophotometric titrations for estimating the oxidizing equivalent of the complex. These were done in the optimum *p*H range. Typical results are given in Table 1, which shows that when ferrocyanide is added to the complex, one ferrocyanide ion reacts per molecule of the complex. The complex thus has only one oxidizing equivalent compared with the two oxidizing equivalents of the peroxide itself. On the other hand, when varying amounts of ferrocyanide and metmyoglobin are mixed and peroxide is added, the full oxidizing capacity of the peroxide appears, as shown in Table 2. This suggests very strongly that the formation of the complex occurs as follows:

$$\underset{(2\text{ oxid. equiv.})}{\text{MetMb} + H_2O_2} \rightarrow \underset{(1\text{ oxid. equiv.})}{\text{Complex}} + \underset{(1\text{ oxid. equiv.})}{X} \qquad (2)$$

and that a transient oxidizing entity is produced which can react with added reducing agents if present initially, but which disappears if the complex formation is allowed to proceed independently.

These results indicate that the complex cannot be of the ion-pair type MetMb—OOH, for such a compound would have two oxidizing equivalents.

Table 2. PEROXIDE ADDED TO MIXTURES OF METMYOGLOBIN AND FERROCYANIDE AT *p*H 8·0

(Initial metmyoglobin and peroxide concentrations 1 04 × 10⁻⁴ *M* and 1 01 × 10⁻⁴ *M* respectively)

$Fe(CN)_6^{4-}$ × 10⁵ *M*	Complex formed × 10⁵ *M*	*Oxidizing equivalents of peroxide accounted for, × 10⁵
0	9·1	9·1
12	7·2	19·2
14	5·6	19·6
16	3·8	19·8
		Equivalents present initially, 20·2

* On the basis 1 mol. complex ≡ 1 mol. $FeCN_6^{4-}$ ≡ 1 equiv. H_2O_2.

A tentative mechanism which can account for these results is the formation of an OH radical and 'ferrylmyoglobin' in a reaction of the type:

$$Fe^{+}(H_2O) + H_2O_2 \rightarrow \underset{(\text{complex})}{FeO} + \underset{(X)}{OH} + H_2O + H^{+}, \qquad (3)$$

where Fe⁺ represents the hæmatin iron atom of metmyoglobin. Ferrylmyoglobin would be a compound of quadrivalent iron, analogous to the ferryl ion and the vanadyl ion, and thus have one oxidizing equivalent when reduced to a ferric compound. The observation by Keilin and Hartree[3] that with excess peroxide the complex is converted into oxymyoglobin could be explained by the further reaction of ferrylmyoglobin:

$$\underset{(\text{complex})}{FeO} + H_2O_2 \rightarrow \underset{(\text{oxymyoglobin})}{FeO_2} + H_2O. \qquad (4)$$

This tentative mechanism may also be applicable to some of the complicated reactions of the peroxide complexes of the enzymes peroxidase and catalase. With peroxidase the green complex formed initially from equal amounts of enzyme and peroxide[6] may have the ion-pair structure and break up as in reaction 3, giving the second complex, pale red in colour. This complex with excess peroxide gives a third complex[7], deep red in colour, which according to reaction 4 would have an oxymyoglobin type of structure. Spectroscopic similarities, however, between this third complex (not the second complex) and the metmyoglobin complex may mean that the enzyme system is different.

Monolayers of Synthetic Protein Analogues

SINCE the natural proteins consist of various amino-acids and their structures are very complex, it is desirable, in order to elucidate their structures and their physical and chemical behaviours, to synthesize simple protein analogues having any particular characteristics of protein molecules[1]. As part of this object, we have synthesized several polypeptides having normal aliphatic side-chains with various numbers of carbon atoms and studied the surface films of these polypeptides spread on water. These polypeptides were easily synthesized from the corresponding normal fatty acids by the N-carboxyamino-acid anhydride method, and have molecular weights of about two hundred thousand. The effects of various solvents and catalysts on the course of

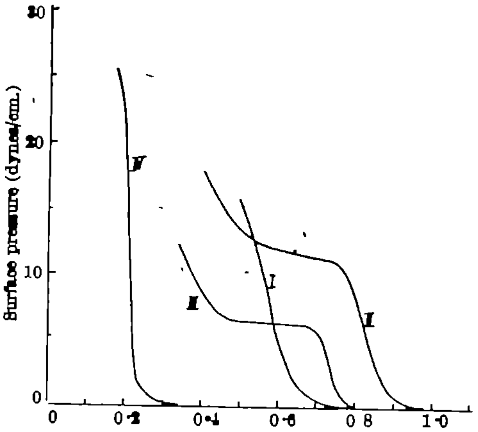

Fig. 1. I, Poly-DL-α-aminocaproic acid ; II, poly-DL-α-aminocaprylic acid ; III, poly-DL-α-aminolauric acid ; IV, poly-γ-methyl L-glutamate

the polymerization of N-carboxyamino-acid anhydrides have already been reported elsewhere[2]. The surface film of poly-γ-methyl L-glutamate spread on water was also studied. The results obtained with surface films spread on water will be briefly described.

The polymers used in our present investigation are poly-DL-α-aminolauric acid, poly-DL-α-aminocaprylic acid, poly-DL-α-aminocaproic acid and poly-γ-methyl-L-glutamate. First, the force–area relations of these polypeptides were examined (Fig. 1). The curve for poly-DL-α-aminocaproic acid resembles very closely those given by ovalbumin and by pepsin film[3]. The limiting area of this curve is about 0·8 m.²/mgm. When the side-chains are longer, as in the cases of poly-DL-α-aminolauric and of poly-DL-α-aminocaprylic acid, a plateau, which is a region of very high compressibility, appeared in the force–area curves. When the area per amino-acid residue was plotted instead of the area per milligram polymer, the force–area relations were changed as indicated in Fig. 2 ; the longer the side-chains, the larger is the limiting area. Among the long and short side-chains found in the films of synthetic polypeptides, the longer ones contribute to the plateau appearing in the graphs. This is remarkably different from the steep inclination of curves resulting from shorter side-chains in films of natural proteins. The mean number of carbon atoms in the side-chains of natural proteins amounts to about three or less. It seems to us that the appearance of the plateau in the force–area curves is related to the length of the side-chains. No plateau was found in the force–area curves for poly-DL-α-aminocaproic acid and for poly-γ-methyl L-glutamate. These polymers have side chains of four carbon atoms.

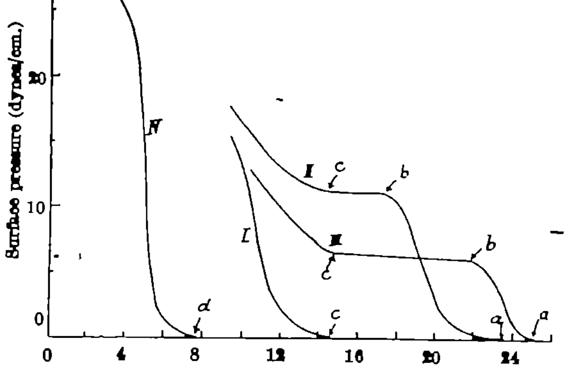

Fig. 2. For key to curves, see Fig. 1

The shape and the limiting area of the force–area curves for poly-DL-α aminocaprylic and poly-DL-α-aminolauric acid changed considerably with time elapsed after spreading the monolayer on the substrate before measurement ; on the other hand, there was scarcely any change with monolayers of polymers with shorter side-chains.

For areas larger than that indicated by point *a* (Fig. 2), the polypeptide molecules were spread with chains flat on the surface. Between *a* and *b*, the surface pressure would be exerted mainly by the action of side-chains. From *b* towards *c*, the surface pressure remained practically constant. It suggests that the molecules of polypeptide are re-orientated in this region and the side-chains compressed away from the surface, so that they are forced upwards or downwards into the water. At point *c*, the area per residue is 14·7 A.². This corresponds to an area of —NH—CH—CO— residue in the closest packing of an arrangement of β keratin configuration. From *c*, the pressure was again increased by further compression. Thus, either the configuration of the backbone of the polypeptide had been changed from the β- to the α-type, or segments of the chain had left the surface. For the film of poly-DL-α-aminocaproic acid as well as that of ovalbumin, the re orientation of the molecules is easier than for the polypeptide films of the longer side chains, because of the shortness of the side-chains. This explains the absence of the plateau in the force–area curves for poly-DL-α-aminocaproic acid and proteins.

The limiting area per residue for the film of γ-methyl L-glutamate polymer is 7·5 A.². This is just half the area per residue of closely-packed chains of β-configuration. It is known that this polymer has a folded structure[4], and the copolymer of γ-methyl L-glutamate with phenylalanine has also the α_{II} configuration[5]. The latter polymer has the α_{II} structure even in a stretched state. This is in good agreement with our experimental results obtained by the surface-layer technique.

A Colorimetric Method for the Determination of Sugars

VOLUMETRIC procedures have been used for the quantitative determination of sugars after separation by partition chromatography[1,2]. It has been our experience that these methods not only require considerable skill, but also they are lengthy and sensitive to slight variation of the conditions. We have therefore attempted to develop a simple quantitative colorimetric procedure. Preliminary experiments showed that the anthrone[3] and the α-naphthol sulphonate[4] reagents give good results with pure sugar solutions, but the presence of only traces of solvents such as butanol, phenol and propionic acid used in the chromatographic separation of the sugars rendered them useless.

It was then discovered that phenol itself in the presence of sulphuric acid provides a simple rapid method for the quantitative colorimetric determination of ketoses and aldoses and their methyl derivatives on a sub-micro scale. The method, applicable to all carbohydrates with either a free or potential reducing group, is particularly useful for determining sugars which have been separated by partition chromatography using phenol–water as the solvent. The orange-yellow colour, produced by adding sulphuric acid (5 ml.) to the sugar solution (2 ml.) containing phenol, is permanent; its optical density (measured at 490 mμ for hexoses and hexuronic acids and their derivatives and at 475 mμ for pentoses and their derivatives) when referred to a standard curve gives the concentration of the sugar.

This phenol–sulphuric acid reagent, which has enabled us to determine the composition of polysaccharides and their methyl derivatives on as little as 1 mgm. of material, thus offers an additional method for end-group analysis of polysaccharides[6]. The reaction is not limited to phenol, for certain amines such as N(1-naphthyl) ethylene diamine can replace phenol in the above reaction.

In conjunction with the above colorimetric method, it has been found convenient to extract the sugars from the strips of paper cut from the chromatogram by simply immersing them in water. Since the extraction is carried out at room temperature, there is no danger of decomposing the sugars[5]. Substances in filter paper which interfere with the sugar analysis can be largely removed by three or four 'chromatographic' washings with water; washing with dilute sodium hydroxide does not seem to improve the paper.

Further details of this work and its application to the determination of the structure of various polysaccharides will appear elsewhere.

A New Paper Chromatography Solvent for Amino-Acids

PHENOL and collidine have remained the most widely used pair of solvents for two-dimensional paper chromatography of amino-acids since their introduction by Consden, Gordon and Martin[1]. The use of the latter solvent, however, is attended by certain disadvantages such as double spots and haloes[2], an offensive smell and possible toxic effects[3,4] and, in some countries, difficulty of supply. Alternative solvents have been suggested, for example, butanol – acetic acid[5], acetone – water[3] and pyridine – amyl alcohol[6]. Some defects of the latter system have recently been reported[7].

A new solvent giving an extremely wide distribution of R_F values is mesityl oxide, which has already been mentioned as a possible solvent for the paper partition chromatography of organic acids[8]. The difficulty encountered by Lugg and Overell[8], namely, the condensation of the solvent in the presence of formic acid, has been obviated by the use of re-distilled and fractionated solvent[9]. Because of the tendency to form peroxides on prolonged storage in contact with air, each batch of solvent should be tested for their presence before distillation. The fractionated solvent (b.p. 129–130°) alone does not give any movement of amino-acids; but the acid spots move when formic acid is added to the solvent system. The method of preparation of the most desirable mobile phase is to shake one volume of the solvent with one volume of formic acid (85 per cent) and two volumes of water. R_F values for the amino-acids in such a solvent are listed in the accompanying table, from which it can be seen that the spread of values is considerably higher than with collidine, and indeed almost as high as with phenol. An additional advantage with this solvent is its rapidity of migration, the solvent ascending about 50 cm. in twenty hours on Whatman No. 1 paper.

R_F VALUES OF AMINO-ACIDS

Amino-acid	R_F	Amino-acid	R_F
Alanine	0·35	Methionine	0·61
Arginine*	0·19	*nor*Valine	0·58
Aspartic acid	0·17	Ornithine†	0·08
Cystine	0·06	Phenylalanine	0·72
Glutamic acid	0·20	Proline	0·89
Glycine	0·22	Serine	0·20
Histidine	0·07	Threonine	0·26
*iso*Leucine	0·70	Tryptophane	0·81
Leucine	0·71	Tyrosine	0·63
Lysine	0·23	Valine	0·58

* Applied as monohydrochloride. † Applied as hydrobromide.

The tendency for mesityl oxide gradually to oxidize and polymerize on standing, with the formation of coloured substances, has been especially noticed in the acidified mobile phase, which after several days may develop a slight orange coloration. This difficulty has been avoided by making up small volumes of the mobile phase just prior to use and discarding any residual solvent after about two days. By this means an exceedingly high degree of reproducibility in R_F values has been obtained. Our usual practice is to allow the paper to become equilibrated thoroughly in the vapours of the stationary phase before introducing the mobile phase. The paper may be quickly and satisfactorily air-dried. Heating of the ninhydrin-sprayed sheet then brings up the spots in their characteristic colours. As with carboxylic acids, spots obtained are discrete and should lend themselves well to quantitative studies[9]. All the chromatograms have been run as with other solvents, although it has been stated that prolonged breathing of the fumes should be avoided[10].

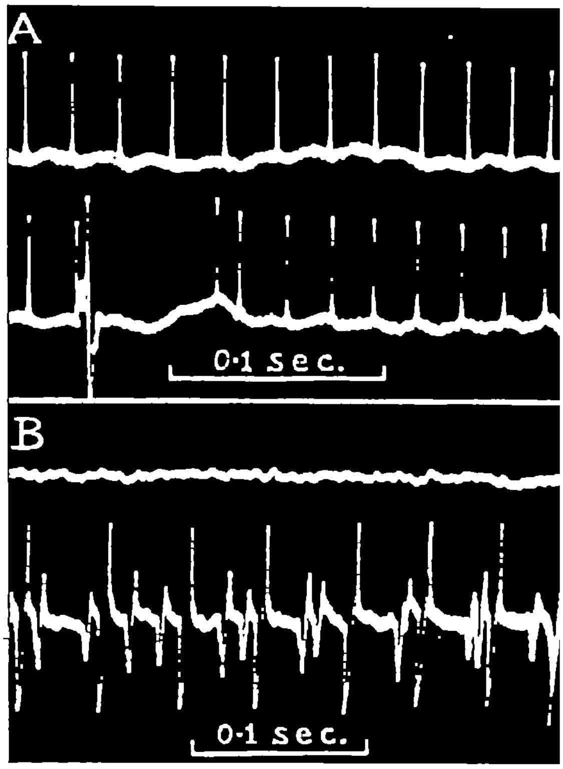
Afferent Limb of the Myotatic Reflex Arc

Within the past decade, the use of electronic methods has laid bare much of the mechanism underlying the myotatic, or stretch, reflex of mammalian striated muscle. Outstanding among these advances are Lloyd's demonstration of the monosynaptic nature of the myotatic reflex pathway, and his disclosure that fibres of large diameter (Group I fibres) constitute the afferent limb of this reflex arc[1]. However, the specific receptor organ responsible for initiating the stretch reflex has so far eluded positive identification, though the balance of evidence suggests muscle spindles rather than Golgi tendon organs[2].

Recently, Szentagothai[3] has brought forward histological evidence indicating that afferent fibres from spindles in the jaw-closing muscles enter the brain stem by way of the *motor* root, while those from Golgi tendon organs pass through the *sensory* root of the trigeminal nerve; furthermore, according to this author, the monosynaptic pathway for the masticatory muscles is completed by way of collaterals from the afferent fibres serving muscle spindles. These observations are difficult to reconcile with the conclusions of Rioch and Lambert[4], who state that the afferent pathway for the jaw-jerk lies in the sensory root of the trigeminal nerve. An attempt to resolve this apparent contradiction has therefore been made in a series of experiments on the trigeminal system in decerebrate cats, and the present communication summarizes the principal results of this investigation.

First, by means of a standard amplifier and oscillograph, an abundance of afferent impulses from stretch receptors in the jaw muscles has been recorded from the peripheral end of the severed motor root of the fifth cranial nerve. Fig. *A* (upper record) shows the discharge of one such ending when the masseter muscle is subjected to moderate stretch. The low mechanical threshold of these stretch endings, and the 'silent period' they exhibit during twitch of the muscle in which they lie (Fig. *A*, lower record), identify them as muscle spindle receptors[5]. This aspect of Szentagothai's findings thus receives oscillographic confirmation.



A. Decerebrate cat. Above: typical stretch receptor discharge elicited by moderate stretch of the masseter muscle and recorded from a fine filament dissected from the peripheral end of the severed motor root of the trigeminal nerve. Below: cessation of discharge from the same receptor during twitch of the masseter muscle. *B*. Decerebrate cat. Electrodes on the exposed lateral surface of the masseter muscle. Above: virtual absence of motor unit activity with the jaw supported in the closed position. Below: typical stretch reflex discharges of several motor units in the same muscle during moderate stretch of the latter after complete severance of the sensory root of the ipsilateral trigeminal nerve

Secondly, after severing the sensory root of the trigeminal nerve in other preparations, the motor root remaining intact, the stretch reflex in the masseter muscle was found to be as active as before (Fig. *B*, lower record). Both the afferent and efferent limbs of this reflex arc must therefore lie in the motor root, which, as Szentagothai has shown[3] carries afferent fibres from muscle spindles only.

The results of these experiments are, therefore, in full agreement with Szentagothai's histological findings, and can be regarded as providing direct physiological proof that muscle spindles and not Golg tendon organs are the stretch-sensitive structures specifically concerned in eliciting the myotatic reflex. No certain explanation can be advanced for the contrary observations of Rioch and Lambert[4]; but it may be noted that, in two of the present experiments, the operation of cutting the sensory root apparently abolished the jaw-jerk. In view of the preservation of this reflex in the remaining experiments, despite complete (and, in some cases, bilateral) severance of the sensory root, it can only be concluded that such atypical results were brought about by unintentional damage, inflicted during the operation, to structures other than the sensory root. Although Szentagothai's studies[3], and the experiments described above, together establish that muscle spindles are indeed the receptor organs responsible for the stretch reflex, it has not yet proved possible to examine separately the reflex effects of impulses arising from the two types of spindle ending[5]. However, in view of the large size of the afferent fibres terminating therein, it is reasonable to conclude that the *primary*, or annulospiral, endings are the actual receptors within the muscle spindles which form the starting point of the myotatic reflex arc.

Inhibition of the Hypophysis of the Guinea Pig by Ultra-Sound Waves

ULTRASONIC irradiation of the brain has been carried out both for diagnostic and for therapeutic purposes[1]. In the dog, neither electroencephalographic nor histological changes are elicited by ultrasonic irradiation, probably on account of the great absorption of the radiation mainly by the bones of the skull[2]. Since, as earlier observed[3], ultrasonic irradiation of the hypothalamus produced respiratory and circulatory changes, it was decided to examine the effects of irradiation of the pituitary gland. Guinea pigs were used for the experiments, partly because surgical hypophysectomy is almost impossible in this animal and therefore, in case of success, irradiation of the pituitary might prove an interesting and simple method of obtaining hypophysectomized guinea pigs.

Eleven animals, approximately fifteen days old, were grouped in five lots, the first consisting of three twin brothers, the other four comprising two twin brothers each. One of each group was kept as control while the other animals were exposed every other day to irradiation with ultrasonic waves, frequency 800 kc./s., intensity 10–40 watts, time 10 min. and radiant surface 2·5 $cm.^2$. Paraffin oil was employed as intermediary substance. The emitter was placed on the central part of the skull. As the radiation proceeded, the animals exposed to this irradiation showed defective growth compared with their controls, which doubled their weight in the same time.

The irradiated animals carried out movements with great difficulty and sometimes lost their equilibrium. Remarkable changes in the skin were also observed, such as ulcerations and loss of the hair, which looked short, frail and bristle. Radiographic examination (Fig. 1) revealed in the irradiated animals a general decalcification, a decrease of the bone trabeculæ, the vertebræ and all the bones in general being of reduced size. Ossification centres were small and badly ossified.

Examination of the adenohypophysis (Fig. 2) showed a noticeable congestion, with widened capillaries occupying a large proportion of the gland. The cells remaining between these vessels had only a little cytoplasm, frequently vacuolated; the large basophile cells were almost entirely absent; and there were abundant acidophile cells with pycnotic nuclei. This nuclear disposition was remarkably frequent and could also be observed in some chromophobe cells and in many of the pars intermedia. In the thyroid a great number of follicles seemed inactive, of large size with a flat epithelium and a dense colloid substance, both scarcely retracted and vacuolated. The adrenal cortex showed somewhat retracted cells in its fascicular zone with homogeneous cytoplasm almost

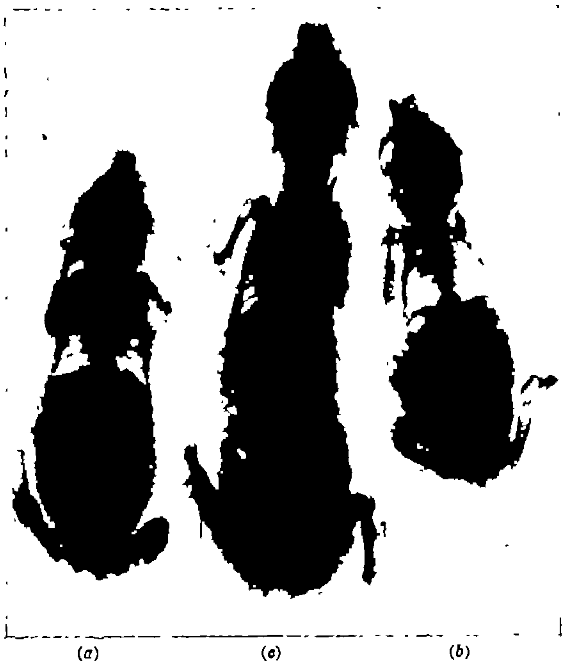

Fig. 1. Radiographs of triplet guinea pigs after two months of ultrasonic treatment of the pituitary gland. Exposures: (*a*) 20 watts; (*b*) 40 watts; (*c*) control. Weights of these animals were: (*a*) 215 gm., (*b*) 200 gm., and (*c*) 350 gm. Lengths of the skeletons were (*a*) 16 cm; (*b*) 14 cm.; (*c*) 21 cm.

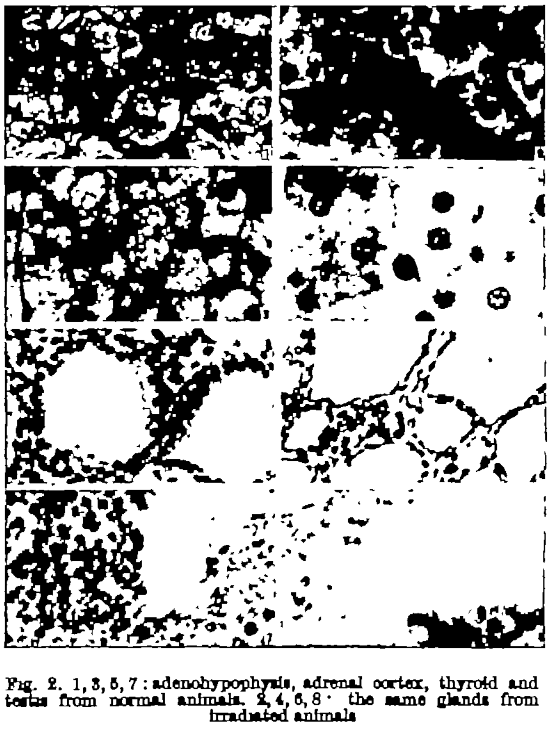

Fig. 2. 1, 3, 5, 7: adenohypophysis, adrenal cortex, thyroid and testis from normal animals. 2, 4, 6, 8: the same glands from irradiated animals

free of lipidic inclusions. The reticular zone of the gland was much congested; nearly every cell showed a pycnotic nucleus, and many were overcharged with pigmentary inclusions. In the testis, a number of seminiferous tubules were atrophied, and the cells of the spermatic series were arranged in only one or two rows. Cells in the condition following the primary spermatocyte had disappeared, with the consequent diminution of the number of mature spermatozoa. Many cells had pycnotic or lytic nuclei. The interstitial tissue was frankly atrophied.

Post-mortem examination of these animals revealed that all the viscera were atrophied, especially the glands, the weight and dimensions of which were much less than those of the controls. The pituitary gland and the fossa pituitaria were relatively small, and the testes were reduced to a third of the normal.

Irradiation of the hypophyseal zone with high doses of X-rays had no appreciable effect on guinea pigs during the growth period. Thus, a guinea pig of 200 gm. exposed to X-rays twice weekly during a fortnight (totalling 1,600 r.), grew to 410 gm. after 45 days. In the same period its unexposed twin brother, the initial weight of which was 230 gm., reached 420 gm. in the same period.

It may be concluded that ultrasonic irradiation constitutes an excellent and bloodless method of affecting the hypophysis of the guinea pig, so as to obtain animals with pituitary insufficiency. It may be possible to apply this method to bigger animals.

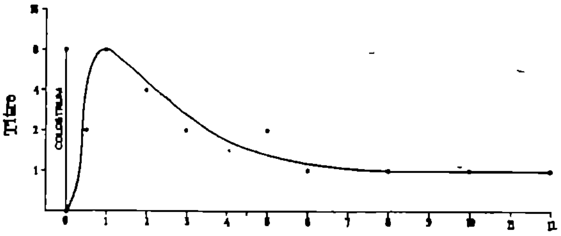
Absorption of Anti-Nematode Antibodies from Ewe's Colostrum by the New-born Lamb

During experimental work on helminth immunity, it was observed that the sera of month-old worm-free lambs gave positive reactions for anti-nematode antibodies. When this observation was made, all the available ewes but one had lambed. A small-scale test was made to determine whether antibodies to parasitic nematodes could be detected in the colostrum of nematode-infected ewes and whether their offspring acquired these antibodies as a result of suckling.

A colostrum sample was taken from a parturient ewe and serum samples were collected from the lamb at birth, that is, prior to suckling, three days later, and then at weekly or fortnightly intervals for three months. The lamb was allowed to run on pasture with its dam; but, though exposed to nematode infestation, eggs could not be detected in its fæces.

All sera and the colostrum were stored at − 20° C. until the end of the experiment. They were then titrated by means of the hæmolytic complement-fixation test. The antigen used was prepared from a mixed culture of *Cooperia curticei* and *Strongyloides papillosus*, following the technique described by Stewart[1].



The results (see graph) showed that the colostrum contained antibodies of relatively high titre. The serum of the new-born lamb did not contain any demonstrable antibodies until after suckling. The antibody titre reached a maximum at one week. During the next five weeks it decreased to a low level, which was maintained for at least three months.

These observations show that anti-nematode antibodies can be transmitted in a manner similar to the more commonly identified antibodies.

Whether the antibodies in the lamb's serum are related in any way to a resistance to nematode infestations has yet to be investigated.

Changes in Electrical Conductivity during Bacterial Growth

Parallel measurements of the electrical conductivity and bacterial count in a solution containing glucose and peptone, in which a small amount of inoculum of *Bact. subtilis* has been introduced, show the typical lag, logarithmic and stationary phases and have brought out the striking result that, even before the multiplication of bacteria takes place, there is an appreciable increase in conductivity. This result is to be attributed to the initial activity of bacteria through their multi-enzyme systems in splitting up the peptone in the medium into amino-acids, which are absorbed by the bacteria from the surrounding medium and provide the nutrient material for their growth. Chemical estimation of the amino-acids formed in the medium revealed a close parallelism between their concentration and the electrical conductivity of the suspension at various stages of bacterial growth. This investigation has thus clearly shown that amino-acid formation takes place through bacterial action in the medium before the bacteria begin to multiply.

The observation mentioned above provides evidence for the view that substances are passed from the cells into the medium during the lag phase, a view which is also supported by another observation o ours that the conductivity of a suspension of washed bacteria in 'conductivity water' increases exponentially with time for about six hours, although thi increase is comparatively small, being about $0{\cdot}2 \times 10^{-12}$ mho per bacterium on the average.

Apyrases of Moulds

THE mycelial mats of *Aspergillus niger* and *Penicillium chrysogenum* possess apyrase activity. The organisms were grown as surface cultures on synthetic media, and at regular intervals the mat was analysed for apyrase activity and for '7-minutes phosphate' in the acid-soluble fraction. During the first phase of metabolism, when sugar was being rapidly consumed, the enzymic activity and the content of labile phosphate were high. When autolysis set in there was a marked drop and sometimes even a complete disappearance of both apyrase activity and labile phosphate. Apyrase probably plays an important part in the metabolism of the mould.

Estimation of enzymic activity in culture solutions was rendered difficult because of the presence of orthophosphate; but at no time was the enzyme concentration high.

Considerable variation existed in the apyrase activity of different strains. The pH – activity relationship was different for *Aspergillus* and *Penicillium*.

Apyrase activity of the mycelium could be extracted by grinding with water in the Waring blendor. The apyrase of *Aspergillus niger* has been concentrated about 450-fold by fractionation with ammonium sulphate. A colourless solution was obtained which was free from glucose oxidase. The enzyme preparations were inhibited by both calcium and magnesium ions at a final concentration of $M/100$. This is in contrast to the marked stimulation of potato apyrase by added calcium ions[1]. Tests with inorganic pyrophosphate showed that the purified enzyme possessed powerful pyrophosphatase activity also. The relative speed of dephosphorylation of inorganic pyrophosphate and adenosinetriphosphate remained fairly constant without any sharp break during the various stages of purification of the enzyme.

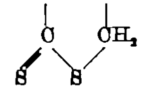
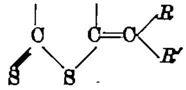
Mildew-preventing Activity of Rhodanine Derivatives

ALTHOUGH rhodanine (I) has some fungicidal activity[1], it was found to be ineffective as a mildew- or rot-preventing agent on cotton cloth. Through condensation of rhodanine with aldehydes and

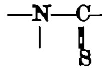


I



II

ketones, derivatives (II) having marked mildew-proofing activity may be obtained. More than a hundred such derivatives have been prepared and tested in our laboratory. It is interesting to note that the new mildew-proofing agents contain the structure $-\underset{|}{N}-\underset{\overset{\|}{S}}{C}-S-$ present in many plant fungicides (tetramethylthiuram disulphide and the salts of dithiocarbamic acid), as well as a carbonyl group conjugated with an ethylenic linkage, found in another class of fungicides[2].



Uniform strips of dyed herring-bone cotton twill were impregnated with 2 per cent of the fungicide under examination and incubated for two weeks on mineral salts agar with pure cultures of *Aspergillus niger* and *Chaetomium globosum*. Other such strips were buried for two weeks or four weeks in soil. In each case the percentage loss in tensile strength was determined.

The majority of the compounds of type II tested were effective in preventing deterioration of the cloth in the pure culture tests (less than 5 per cent loss in tensile strength). Eighteen of the compounds afforded similar protection in the two weeks soil burial test. Under the same conditions cloth strips impregnated with chloranil lost 80 per cent or more of their tensile strength.

In four weeks soil burial tests, the most active five compounds were the 2-thenylidene-, p-methyl*cyclo*hexylidene-, α-n-amylhexylidine-, o-methyl*cyclo*hexylidene- and p-chlorobenzylidene-rhodanines. All these prevented tensile strength losses greater than 25 per cent.

Details of this work, which was supported by a contract with the Medical Division, Chemical Corps, U.S. Army, will be reported elsewhere.

Improved Sampling Method for Demonstration of Local Antibodies in the Vagina

IN infections with pathogens of low virulence strictly localized to a few or single organs, it is often difficult, if not impossible, to obtain reliable diagnostic findings by means of tests for antibodies circulating in the blood stream. This holds true in particular if only some parts of a mucous membrane are involved. In such cases, however, it may prove practicable to utilize the local antibody production for diagnostic purposes.

Serological examination of vaginal mucus has been employed by Pierce[1] for the diagnosis of bovine trichomoniasis, and by Stegenga and Terpstra[2] for the diagnosis of vibriosis (due to *Vibrio fœtus*). The local production of antibody has also been used to detect bulls with brucellosis localized to the genitals[3].

The procedure hitherto employed for collection of vaginal mucus by suction with a glass tube is cumbersome as well as time-consuming; besides, it is applicable only to cows with sufficient secretion in the vagina. On the other hand, on account of its great dilution, the usually abundant œstral discharge is less suitable for the demonstration of antibodies. Therefore, this sampling technique is not very serviceable for routine examination.

A gauze tampon (about 15 cm. × 19 cm., weighing 1·1 gm.) placed in the fundus of the vagina will absorb on an average about 3 gm. of secretion, and even when the vagina is 'dry' the tampon will take up about 1 gm. This rather wide variation has no influence upon the outcome of the routine examinations, and, if desired, corrections for the variation can be made by means of dilution. The fluid absorbed by the tampon can also be used for bacteriological examination.

Technique. A piece of gauze, about 15 cm. × 19 cm., weighing about 1·1 gm., is rolled up, tied with ordinary string and wrapped around the end of a thin stick, while the end of the string is tied around the other end of the stick. This swab is then packed in paper and sterilized. For sampling the secretion in the vagina, the tampon is placed in the fundus, for example, through a speculum or by means of a tube made for this purpose[4]. Then the stick and the speculum are removed. After 20–30 min., the tampon is pulled out by means of the projecting end of the string, the vulva being kept wide open. The sample is placed in a glass tube. The secretion is extracted by 4–6 ml. of distilled water or saline. For the various tests, some of this extract is withdrawn by means of a pipette.

This tampon method has proved serviceable in practice in examinations for the presence of antibodies against *Vibrio fœtus*. It has also proved practicable in this way to demonstrate the presence of complement-binding antibodies against pleuropneumonia-like organisms isolated from the same tampon samples taken from a herd with pronounced post-œstral discharge and difficulties in fertilization. (On examination of the blood serum, Edward[5] was unable to demonstrate any complement fixation with homologous strains.)

It may be possible by means of this technique also to throw some light on the much disputed question in human medicine about the relation between unspecific vaginitis or urethritis and pleuropneumonia-like organisms.

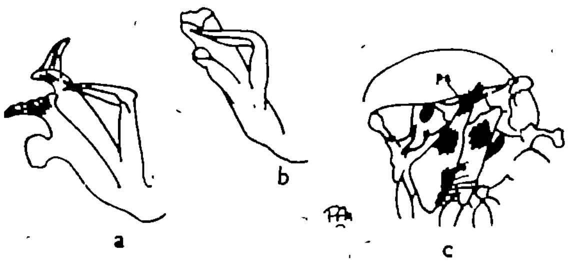
Culex (Culex) torrentium Martini, a Mosquito New to Great Britain

FOURTH instar larvæ and pupæ referable to *Culex* (*Culex*) *torrentium* Martini were taken in some abundance from water-tanks on allotments at Isleworth, Middlesex, by Mr. Bowles, of the Health Department, on June 19 of this year. They were sent for identification, together with emergent adults, to the British Museum. The name *torrentium* is applied provisionally since, as Natvig[1] has pointed out, the synonymy of the group is somewhat obscure and requires further investigation. There can, however, be little doubt that this is the Scandinavian species described by Natvig as *torrentium*.

The principal difference between this species and *C. pipiens* lies in the structure of the phallosome, which is absolutely diagnostic (see diagram). Among external characters the best for diagnostic purposes is the presence in *torrentium*, but not in *pipiens*, of a prealar scale patch at the tip of the sternopleura.



Culex spp. *a*, *c*, *C. torrentium* Martini, *b*, *C. pipiens* Linnaeus. *a*, *b*, lateral plates of phallosomes; *c*, side view of thorax; *pa*, prealar scale patch

This character has not previously been applied to the Palæarctic *Culex* but was used very successfully by Edwards[2] in dealing with the Ethiopian species. It is considered that it will almost certainly prove to be reliable. Natvig considers certain small differences in wing venation to be diagnostic. The stem of the upper fork cell is said to be about a quarter to a third the length of the fork itself in *torrentium* and a fifth to a sixth the length of the fork in *pipiens*. In *torrentium* the radio-medial cross vein is said to be placed about twice its length distally to the mediocubital cross vein. In *pipiens* it is said to be about one and a half times its length distal to the mediocubital cross vein. It is not known whether these characters will prove to be constant in British populations.

The Isleworth form is quite strikingly different from *pipiens* with respect to certain colour characters, notably the presence in most specimens of far more numerous dark scales on the abdominal sternites. It is, however, a very dark form as compared with topotypic specimens from Thuringia in the British Museum and, as dark and light forms are extremely common in the genus *Culex*, colour differences are of doubtful value. It exhibits numerous pale scales on the underside of the male palps, as does the Scandinavian form, but these would probably be much less conspicuous in a light variety. A few small larval differences are given by Martini[3], who refers to *torrentium* under the name *exilis* Dyar. These may or may not prove constant.

It is not known whether *C. torrentium* bites man; but many members of the *pipiens* group do so. The normal breeding places are fresh natural waters of various kinds; but Natvig has a record—comparable with the present one except that in his case the water was very foul—from a garden pail. It is not known whether this is a recent introduction into Great Britain or whether the species has previously escaped detection owing to its resemblance to *pipiens*. The former explanation is thought to be more probable. If this is a rare, though established, species, it is possible that its detection may have been due to a local increase in population arising from some unusual chain of favourable climatic conditions. In either event it seems desirable to direct attention to its presence in Britain, so that a search may be made for it in other localities.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned

Lecturer in the Electrical Engineering Department (industrial experience on the power side of electrical engineering is essential)—The Secretary of University Court, The University, Glasgow (August 7).

Deputy Mechanical Engineer (with a university degree in Engineering, or corporate membership of either the I.C.E., I.M.E., or I.E.E.)—The Engineer and Manager (General), Sunderland and South Shields Water Company, 29 John Street, Sunderland (August 10).

Development Engineer in the Production Department at London headquarters—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting TT/359 (August 11)

Lecturer in Physics—The Secretary, Royal Technical College, George Street, Glasgow, C.1 (August 11).

Scientific Officer (Physicist with interest in aerodynamics or Mathematician prepared to do experimental work, with a first- or second-class honours degree or equivalent qualification) for theoretical and experimental duties in connexion with marine aircraft performance, etc. (Ref. 199/51A), and an Experimental Officer (with H.N.C. or equivalent qualification in electrical or telecommunications engineering, preferably with experience in the design and maintenance of aircraft electrical systems) (Ref. D.316/51A), at a Ministry of Supply experimental establishment in Suffolk—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (August 11).

Soil Research Officer in the Irrigation Branch, Punjab Public Works Department, Lahore—The High Commissioner for Pakistan, 35 Lowndes Square, London, S.W.1 (August 13).

Assistant Advisory Officer (Grade IVa or IVb) in the Bacteriology Department, an Assistant Adviser in Horticulture, and a Fruit Trials Officer (Grade III or IVb) in the Horticulture Department—The Secretary, North of Scotland College of Agriculture, 41½ Union Street, Aberdeen (August 15).

Lecturer in Physics (preferably in Experimental Physics) at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (August 15).

Psychological Assistant in the Department of Psychiatry—The Registrar, The University, Leeds 2 (August 15).

Senior Experimental Officer or Experimental Officer in the Royal Naval Scientific Service—The Secretary, Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4048/51 (August 16).

Senior Scientific Officers (2, with a first- or second-class honours degree in botany and well qualified in systematic botany) at the Royal Botanic Garden, Edinburgh—The Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4046/51 (August 16).

Chemists II (Ref. F.492/51A) with first- or second-class honours degree in chemistry or chemical engineering, or associateship of the R.I.C. or I.C.E., and Chemists III (Ref. F.493/51A) with first- or second-class honours degree in chemistry or associateship of the R.I.C., preferably with specialization in organic chemistry and wide industrial experience, in the Ministry of Supply—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (August 18).

Junior Physical Chemist (with at least two years research experience in physical chemistry, and a first- or second-class honours degree) at the I.C.T.A., Trinidad—The Secretary, Imperial College of Tropical Agriculture, 40 Norfolk Street, London, W.C.2 (August 18).

Lecturer in Mathematics at the University of Sydney—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (August 18).

Research Officer (Biologist) at the Fisheries Research Station, Dunwich, Queensland, to assist in the programme of research on mullet and oysters (Ref. No. 3469), and an Officer-in-Charge, Physical and Mechanical Testing Laboratory, Division of Building Research, Highett, near Melbourne, to undertake and supervise research on physical problems associated with building materials and buildings generally, and to be responsible for physical and mechanical tests on a wide range of building materials (Ref. No. 3470)—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (August 18).

Junior Research Fellowship in the study of hydraulics by means of scale models—The Secretary, The University, Aberdeen (August 20).

Physicist or Electrical Engineer (Principal Scientific Officer grade) with a high-class honours degree, and research experience in telecommunications with special emphasis on all radio telephony methods and high speed telegraphy, a Physicist (Senior Scientific Officer grade) with a high-class honours degree, with research experience and a considerable knowledge of electronic circuitry, and a Physicist or Electrical Engineer (Senior Scientific Officer grade) with a high-class honours degree, and experience in telecommunication research with emphasis on radio telephony and high speed telegraphy problems, in the Royal Naval Scientific Service—The Secretary, Civil Service Commission, Scientific Branch, Trinidad House, Old Burlington Street, London, W.1, quoting S.4049/51 (August 23).

Physicists (Scientific Officer grade) (with a first- or second-class honours degree in physics, and experience in optical and photographic work, preferably using high-speed cameras) at a Ministry of Supply design establishment near London—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting A.188/51A (August 24).

Physicists at a Ministry of Supply research establishment near London, for work connected with the handling and measurement of radioactive materials and associated health physics problems—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting A.200/51A (August 24).

Assistant Director (Engineering) at the Atomic Energy Research Establishment, Harwell, to be responsible to the Chief Engineer for direction and management of large drawing office and particularly of large engineering workshop engaged in the manufacture of wide variety of experimental plant, mostly to high standards of precision—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting C.417/51A (August 25).

Lecturer (graduate, with professional experience) in Civil Engineering—The Registrar, King's College, Strand, London, W.C.2 (August 25).

Operational Research Posts in the Field Investigation Group of the Directorate of Scientific Control—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, endorsed TT/361 (August 25).

Assistant Chemist (with a specialized honours degree, or the A.R.I.C. qualification) in the Department of Geological Survey—The Secretary, Office of the High Commissioner for Southern Rhodesia, 429 Strand, London, W.C.2 (August 31).

Assistant Lecturer in the Department of Biochemistry and Chemistry, to teach inorganic and physical chemistry to first M.B. standard—The Dean, Guy's Hospital Medical School, London Bridge London, S.E.1 (August 31).

Junior Fellow (with veterinary qualifications, and postgraduate experience in the subject would be an advantage) in Clinical Parasitology in the Veterinary School—The Registrar and Secretary, The University, Bristol (August 31).

Lecturer or Senior Lecturer in Mechanical Engineering at the University of Melbourne—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (August 31).

Professional Engineers, General Service Class (Main and Senior grades) in the Admiralty—The Secretary, Civil Service Commission, Trinidad House, Old Burlington Street, London, W.1, quoting S.86/51 (August 31).

Plant Physiologist (well qualified in botany, with specialization in plant physiology) at the Wattle Research Institute, University of Natal, Pietermaritzburg—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (September 15).

Assistant Lecturer (probationary) in Applied Mathematics, and an Assistant Lecturer (temporary) in Philosophy—The Registrar, University College, Singleton Park, Swansea.

Assistant Lecturer and Demonstrator in the Physiology Department—The Secretary, King's College of Household and Social Science, Campden Hill Road, London, W.8.

Civil Engineers, Main Grade (Ref. E.251/51) and Assistant Civil Engineers, Recruitment Grade (Ref. E.252/51), in the Directorate General of Works, Air Ministry, in London and the Provinces—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting the appropriate Ref. No.

Civil, Mechanical and Electrical Engineers for National Defence Projects and developmental works in all States of the Commonwealth and in New Guinea—The Public Service Board Representative, Australia House, Strand, London, W.C.2.

Demonstrator for Electrical Engineering, and Demonstrators (2) for Mechanical Engineering including (a) strength of materials, metallurgy and desirably metrology and (b) applied thermodynamics and mechanics of fluids with preferably aerodynamics—The Principal, Royal Aircraft Establishment Technical College, Farnborough, Hants.

Electrical Engineer (Mechanical) by the Central Electricity Board, Federation of Malaya—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.28370.B.

Experimental Officer (male) to assist in hydrographic research and chemical analysis of sea-water—The Director, Marine Station, Millport, Isle of Cumbrae.

Geologist Stratigrapher with an honours degree in geology (Ref. M.27565.B), and a Marine Biologist with an honours degree in zoology and a knowledge of the establishment of marine fisheries (Ref. M.27588.B), in the Falkland Islands Dependencies Survey for service in the Antarctic—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting the appropriate Ref. No.

Lecturer (a degree in electrical engineering is essential) for work on electrical measurements—The Secretary, Royal Technical College, Glasgow, C.1.

Lecturer in Mathematics—The Clerk, Northern Polytechnic, Holloway, London, N.7.

Physicists, Chemists or Electrical Engineers (well qualified, with postgraduate experience) for basic research on the electrical properties of materials, particularly dielectrics—The Director, Electrical Research Association, 5 Wadsworth Road, Perivale, Middx.

Principal Scientific Officer (with a good honours degree in engineering and some research experience) in the Engineering Division, to undertake investigation of the problems associated with the mechanical harvesting, handling and processing of underwater seaweed—The Secretary, Institute of Seaweed Research, Inveresk, Midlothian.

Senior Water Engineer in the Water Supply and Irrigation Department, Cyprus—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London S.W.1, quoting No. 27322/218.

Soil Chemist (Ref. 4/124), and an Entomologist (Ref. 4/41), in the Research Division of the Ministry of Agriculture, Sudan—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, quoting the appropriate Ref. No

Statistician (with a good degree in mathematics and some industrial experience)—The Divisional Chief Scientist, N.E. Division, National Coal Board, Roundwood Colliery Offices, Parkgate, Rotherham, Yorks.

Telecommunications Engineers and Physicists (Principal Scientific Officer or Senior Scientific Officer grade) at the Royal Aircraft Establishment, Farnborough—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting D.158/51A.

University Honours Graduate (preferably with a degree in organic chemistry) for training as a microanalyst—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, Manchester.

INTERNATIONAL NATURE CONSERVATION

THE English version of the Proceedings and Reports of the second session of the General Assembly of the International Union for the Protection of Nature, which was held in the Solvay Institute of Sociology at Brussels during October 18–23, 1950, has now appeared. The other, the French, version was published somewhat earlier. It is therefore a convenient moment to take stock of the position, to review the course of events which led to the establishment of an international body with the object of preventing the threatened extermination of species or associations of plants and animals, and to survey what has been accomplished and what is contemplated in the future.

The concept that Nature needs protection from the multifarious activities of man was first recognized in comparatively recent times, for it was only in the industrial age, when he had harnessed to his use mechanical power, that the destruction of the wild life of extensive areas was seriously threatened. The first incident to attract the attention of the civilized world was the disappearance in the seventeenth century of the helpless and harmless dodo, not of intent, but through sheer thoughtlessness and negligence. A greater disaster was narrowly averted in the nineteenth century, when with the rapid extension of the cultivation of the prairies of north-west America the bison diminished in numbers with corresponding rapidity. Thanks, however, to the timely action taken by the Governments of the United States and Canada, the animals that still survived were gathered together into safe-keeping in reserves, and the species was saved. Another phenomenon which attracted even wider attention, because commercial interests were involved, was the marked diminution in numbers, almost to the point of extinction, of whales in the Arctic seas. Late in the nineteenth and early in the present century, many nations spontaneously formed societies and took legislative action, in order to safeguard the wild life in their respective countries. It was, however, soon realized that individual action was not enough, and that international co-operation was needed, because in so many instances animals, especially birds, disregarded national frontiers, and it was of little use one country protecting a species if its neighbours destroyed it; moreover, life in the open seas necessarily demanded mutual understanding among the maritime nations.

In the early years of the present century, spasmodic efforts were made to initiate some form of international agreement for the protection of Nature; but beyond the passage of pious but fruitless resolutions they led to no positive results. The celebrated Swiss naturalist, the late Dr. Paul Sarasin, whose name is perpetuated by a tablet on a slab in the Swiss National Park, may justly be said to have laid the foundations upon which others built. At the eighth International Congress of Zoology, held at Graz in 1910, his proposal for an international commission was adopted, and, what is more, a provisional committee was appointed to follow the matter up. As a consequence, in 1913, under the auspices of the Swiss Federal Government, an international conference was held at Berne, and resulted in the adoption of an Act of Foundation of an Advisory Commission for the International Protection of Nature with its seat at Basle. With the ratification of the Act by a sufficient number of nations it looked as if success had been achieved. Unhappily, the First World War supervened, and the movement was not only temporarily brought to a standstill, but was also found impossible of resuscitation on the restoration of peace. Dr. Sarasin did make a determined effort to revive the movement at the International Congress for the Protection of Nature at Paris in 1923, but without definite result; and he died in 1929. His work was, however, carried on by Dr. P. G. van Tienhoven, who had taken a prominent part in securing the protection of Nature in the Netherlands. He was successful in forming the International Office for the Protection of Nature; but, in spite of his valiant efforts, the general response throughout the world was lukewarm, and, although the Office carried on, and indeed still functions, the lack of sufficient financial support has limited its activities to the accumulation of documents relating to the subject.

It may be noted in passing that, although the Second International Congress for the Protection of Nature, held at Paris in 1931, failed to achieve general international co-operation, it led directly to the Conference of the African Powers in London in 1933, which resulted in the Convention for the Protection of the African Fauna and Flora. A very similar convention for Nature protection and wildlife preservation in the western hemisphere was drafted at the Eighth Pan-American Scientific Congress, held at Washington in 1940, and became effective in 1942.

At the close of the Second World War, the Swiss League for the Protection of Nature, mindful of Dr. Sarasin's achievements, bestirred itself, and as a start invited naturalists from various European countries to visit the Swiss National Park and Reserves in the summer of 1946; and at the end of their visit they were induced to discuss informally the international aspect. Stimulated by this experience, the League embarked upon a more ambitious project, and issued invitations to governments, government institutions, and voluntary societies to participate in an international conference at Brunnen in the summer of 1947. The object in view appeared to be the revival of the Act of Foundation of 1913; but the general feeling among the delegates was that it would be a mistake not to take note of the change in political conditions, and especially the creation of the United Nations Organization, and that what was needed was not an Advisory Commission but an international union which could be linked up with the United Nations Educational, Scientific and Cultural Organization (Unesco). An appropriate constitution was accordingly drafted, and, after approval by the Conference, was transmitted to Unesco with the request that it should convene an international conference for the purpose of founding a union. After some hesitation owing to the fact that doubt was felt whether the proposed union might be considered to come within its objects, Unesco agreed and under the joint auspices of it and the French Government an international conference, attended by delegates from thirty-two countries, took place at Fontainebleau at the beginning of October 1948.

As a result of this conference, the International Union for the Protection of Nature was formed with its seat at Brussels, Dr. Ch. J. Bernard being elected president and Mr. Jean-Paul Harroy secretary general. Its constitution was largely based upon the one adopted at Brunnen. Its membership is unusua in character, being a combination of official and private bodies; it is of four classes: (*a*) governments; (*b*) public services concerned with the protection of Nature; (*c*) international (inter-governmental and non-governmental) organizations, institutions and associations concerned with the protection of Nature; (*d*) non-governmental national organizations, institutions and associations concerned with the protection of Nature. In order to assure the over-riding power of governments, in the General Assembly the government of each country has two votes, but all its national bodies together only one vote. In view of this voting arrangement, the British Co-ordinating Committee for Nature Conservation was formed as a committee of the Society for the Promotion of Nature Reserves, in order to formulate a common policy for the non-governmental bodies of Great Britain; the appropriate government departments are, however, represented at meetings of the Committee by observers, as also are certain other British countries. By Treasury regulation, subscriptions to the Union from private bodies have to be transmitted through the Committee, the maximum amount in any one year being restricted.

The first major piece of work to be undertaken by the newly formed Union was, at the request o Unesco, the organization of an International Technical Conference at Lake Success in August 194 concurrently with the United Nations Scientifi Conference for the Conservation and Utilization o Resources. The subjects discussed were groupe under two main headings, education and ecology and a large number of resolutions were adopted fo submission to the General Assembly of the Union The second session of the General Assembly was hel at Brussels towards the end of October 1950, an was attended by 103 delegates representing thirty one countries, together with eighteen observers from eleven international organizations; the actual number of persons present was not so large, because i many instances the same individual represented mor than one body. After consideration of the report o the Union's activities since its formation two year before, the main business was the consideration o the resolutions submitted by the Lake Success Conference, the Unesco representative relating what tha body had already done to implement them. Sinc the success of the Union must ultimately depend upo the public support it is able to attract, an importan step towards this end was taken by setting up a

Educational Section, with wide discretionary powers, at Washington under the chairmanship of Mr. Ira N. Gabrielson. A Survival Service was formed with the object of stimulating measures for the preservation of the species in grave danger of extinction which had been listed at Lake Success. Another important piece of work, which was rendered possible by financial assistance from Unesco, was the collecting and collating of information about the state of Nature conservation in different countries throughout the world; the volume has now appeared. The urgent need for an official periodical to provide information about the Union and its activities was recognized, but the stumbling block which was found impossible to circumvent was the absence of funds adequate to meet the inevitable cost, at least initially.

In fact, the obstacle blocking the Union's progress is the want of adequate financial resources. It is in the grip of the familiar vicious circle: on one hand it is starved of funds, and on the other criticized for apparently doing so little. Under the constitution, government and non-government bodies are expected to subscribe annually 50 American dollars, whereas the subscriptions for governments depend upon the population of their respective countries, ranging from 250 dollars for those with less than 5 million inhabitants to 2,000 dollars for those with more than 20 million inhabitants. It therefore follows that the contribution by the government of a large country is equal to the combined total of forty organizations. Moreover, in the existing difficult circumstances, comparatively few societies can easily afford the unit subscription, in view of the fact that with the rise in costs they can barely meet their commitments. It would obviously make all the difference if governments generally were to adhere to the Union; but unhappily as yet only those of four countries—Belgium, Luxembourg, the Netherlands and Switzerland—have done so. In the United Kingdom the Government has not itself adhered; but the British Museum (Natural History) and the Nature Conservancy have become members. For the sake of the future of the Union, it is sincerely to be hoped that it may be supported by a larger number of governments. In certain instances there may be some hesitation for fear lest the government might be committed to a course of which it did not approve; but this objection has been met by the provision that no government is bound by a decision of the Union, even if at the time it was approved by its own delegates.

A FEAST OF FAREY FRACTIONS

The Farey Series of Order 1025

Displaying Solutions of the Diophantine Equation $bx - ay = 1$. Designed and compiled by E. H. Neville. (Royal Society Mathematical Tables, Vol. 1.) Pp. xxix+405. (Cambridge: At the University Press, 1950.) 105s. net.

THE Farey series F_n of order n is the ascending series of irreducible fractions between 0 and 1 the denominators of which do not exceed n. For example, F_5 is 0/1, 1/5, 1/4, 1/3, 2/5, 1/2, 3/5, 2/3, 3/4, 4/5, 1/1, and so contains eleven terms. The series compiled by Prof. E. H. Neville is F_{1025}; it contains 319,765 fractions and occupies four hundred pages. In addition, tables of F_{50} (with decimal equivalents), F_{64} and of the denominators in F_{100} are given as appendixes. A loose card containing the factors of all the numbers between 1 and 1049 is issued with the volume. The preparation of a table of this magnitude is a considerable feat, and Prof. Neville must be congratulated on having completed such a formidable task.

Farey series have a variety of interesting properties and uses. If a/b, a'/b' and a''/b'' are consecutive fractions of such a series, then (1) a'/b' is the mediant of a/b and a''/b'', that is, $a'/b' = (a + a'')/(b + b'')$, and (2) $ba' - ab' = 1$. Properties of this kind can be used when it is desired to approximate to a given irrational number α by means of a rational number a/b. It is first necessary to find the consecutive fractions a/b, a'/b' of F_{1025} between which α lies; convenient ways of doing this are described. If it is desired to approximate to α more closely than this, the problem becomes essentially that of finding the fractions of a Farey series of higher order which lie between a/b and a'/b'. Prof. Neville shows how this can be done in an economical way by making further use of his main table.

Another use of Farey series is to provide solutions x and y of the Diophantine equation $bx - ay = 1$ for given a and b without a common factor. If b does not exceed 1,025, the property (2) suggests a solution, since the equation is satisfied by $x = a'$, $y = b'$ where a'/b' is the successor of a/b in F_{1025}; other neighbouring terms also give solutions in certain cases. If b exceeds 1,025, the fraction a/b belongs to a Farey series of higher order, and the methods mentioned in the preceding paragraph can be used to provide solutions. In fact, by using the main table, or that of F_{50} with its decimal equivalents, the equation can be reduced by stages to one which is easily solved.

When one is confronted with a work of the magnitude of Prof. Neville's, one cannot help reflecting upon the grounds which justify the publication of tables in the theory of numbers. A list of gear-ratios arranged in order of magnitude is a Farey series, but even the engineers of the distant future are likely to find the scope of the present table beyond their requirements. Thus, so far as can be foreseen, other grounds of justification than those of practical use must be sought. It is possible that some would claim that the compilation of such a table is a contribution to human knowledge and so requires no further justification. Most of us would feel, however, that some discrimination must be exercised, and that the main justification of this kind of work lies in the use made of it. There are at least three different ways in which number-theoretical tables can be used. First, such a table may assist and shorten calculations made for purposes which are conceded to be of importance; a table of prime numbers is an obvious example. Secondly, a table may help to decide the truth or falsity of some important conjecture; Ramanujan's conjecture concerning the magnitude of his function $\tau(n)$ is a case in point. Thirdly, the study of a table may reveal the existence of hitherto unknown properties of the numbers tabulated; thus it was after studying Henry Goodwyn's table of Farey fractions that John Farey observed the mediant property (1), and in more recent times multiplicative properties of arithmetical functions have been discovered in a similar way.

As has been indicated, Prof. Neville's table can be used to solve particular problems of Diophantine analysis. Even a number-theoretician could not pretend, however, that such problems are of common occurrence, although the associated general problems are among the most interesting and difficult in number theory. It may be, of course, that future researches will make extensive use of the table for these or similar purposes. However, in my opinion it is largely for its possible uses to future Ramanujans in suggesting general properties hitherto unnoticed that Prof. Neville's table is justified. Whether such hidden properties do, in fact, exist it is not possible to say, although the recent elegant extension by Mahler, Ledermann and Cassels of Farey series to fractions in certain algebraic fields suggests that the subject is by no means exhausted and that there may still be scope for Farey's "curious calculators".

The book is beautifully printed in the usual competent style of the Cambridge University Press and is very appropriately dedicated to Srinivasa Ramanujan.

R. A. Rankin

THEISM AND THE INDIVIDUAL

The Christian Challenge to Philosophy

By the late W. H. V. Reade. Pp. xiii+195. (London: S.P.C.K., 1951.) 13s. 6d. net.

THIS book is the work of a Fellow of Keble College, Oxford, who died in 1943, leaving his manuscript prepared for publication. The author's character is sketched for us, simply and sympathetically, in a preface by Mr. Cyril Bailey, to whom the reader will be under a considerable debt. We are confronted by the picture of a master mind, embedded in a personality at once saintly, witty, artistic and shy. Mr. Reade cannot have been easy to know; but he made a lasting impression both as a teacher and as an official. Add to these conditions, the evening of a longish life, plus retirement from active academic affairs amid the darkest period of the Second World War, and we have the setting for the composition of these remarkable essays.

Perhaps their most outstanding feature is an utter lack of self-consciousness in following a theme to the bitter end, a theme not merely committed to paper, but lived and tested. To read these pages without realizing all this would be a sad mistake.

So, a beginning is made with the year A.D. 529, when the Emperor Justinian closed the Academy, and Greek philosophy was thereby officially declared to be dead. Oddly enough, we are not escorted forwards chronologically from here, but backwards towards its birth. This process brings to light—among other things—the almost incredible heterogeneity of the Pythagorean society, in which learned men found themselves apparently in close association with incorrigible purveyors of old wives' fables. Yet, in some respects how modern. Music was studied as a theoretical discipline, having little or no regard for composition or technique, and the fact that strong emotions were engendered by "sheer sound" only serves to remind us how primitive the basis must have been.

Nevertheless, philosophy was a way of life; it was, indeed, something to be used, something to be experienced. Above all, it had not yet become a 'subject' for study in the sense assigned to it by a university faculty. Its leaders, however, made a decisive step, commonly unknown, but if recognized, then seriously belittled. They invented theology as a protest against religion; not against established religion, but against all sorts of debased superstitions and myths. Yet theologians themselves must have increased in mental stature at a very uneven rate. Originally they appear as tale-tellers about the gods, nothing more, whereas Aristotle, having early contrasted them with 'physicists', later raises their status to that of a class interchangeable with "first-philosophers" or metaphysicians. Evidently, no longer had they anything to do with myths, and something quite fresh had been added to the Pythagorean outlook. All of which goes to show the complexity of the *logos* concept on its way to become a Christian tenet, central for doctrine and devotion alike.

From here it is a natural step to the fundamental position which this volume takes up regarding the absolute rejection of Platonism by Christianity. There is no half-way house, only complete incompatibility. Plato never seriously considered whether the altars (as he conceived them) about which, some centuries later, the Apostle to the Gentiles made his well-known comment, were dedicated to the one eternal Spirit, or whether their aim was essentially mythical. Thus there is for him (Plato) no theophany in history, no revelation of God "beyond the scope of science" to be uncovered by faith. Closely coupled with these elemental distinctions is Mr. Reade's major demand that religion was never for the few—in particular, the intellectually gifted—but for all from the least to the greatest. Here, certainly, the Christian challenge to philosophy is made manifest.

The reader is invited to study the later chapters of this book more especially if he is interested in modern problems thrown up by twentieth-century civilizations. He would be well advised, however, to receive this considerate suggestion with caution, since an understanding of the medieval scene, brilliantly delineated in the middle sections, is absolutely necessary if any significant judgment is to be reached regarding our present discontents. Incidentally, there is a valuable discussion concerning the relative positions of theology and philosophy in the hierarchy of learning. Mr. Reade avoids the decisive grading of the Western tradition: if philosophy is not exactly a "serving-maid", theology is no more than a first among equals, or perhaps between equals. This is no mere playing with words; it represents very fairly the Anglican position at its best, and markedly so when account is taken of the isolation of scholarship some eight years ago.

Along paths like these, the author approaches the climax of his argument. It amounts to a stern warning against all forms of riding roughshod over the individual, whether that word denotes persons or things. Every person is unique, and to be held in reverence on that account; moreover, many 'things' are unique—objects of great art, for example—and incapable of statistical evaluation. This axiological outlook is of the very core and substance of all Christian striving, and is bound to do battle against any philosophical system involving mass-production, mass-thinking, mass-behaviour, and the rest. It is inappropriate to enlarge upon the purely ecclesiastical functions implicit in such a way of life—suffice it to add that they receive their share of Mr. Reade's erudition and good sense. But there is one phrase (on p. 27), which seems like a slip, namely, "the opinionated man, tenacious and dogmatic . . .". Surely this is, in part, a tautology if the Greek δόξα is accorded its usual rendering.

The proof-reading must have been exemplary, and the format is attractive. This is a book to be bought rather than borrowed. It will not find easy acceptance, nor make rapid converts. But if neglected, it may well be at our peril. F. I. G. Rawlins

PURE AND APPLIED CHEMISTRY OF STARCH

Chemistry and Industry of Starch

Edited by Dr. Ralph W. Kerr. Second edition, revised and enlarged. Pp. xii+719. (New York: Academic Press, Inc., 1950.) 11.50 dollars.

Before the first edition of this book was published in 1944, more than four thousand papers had appeared on the subject of starch, and the late H. E. Armstrong once used the expression "the tragedy of starch" in reference to the subject. Since 1939 matters have changed, and so far as chemical structure is concerned a much clearer picture is now possible, although one would welcome further advances in the physical properties and the industrial applications of starch and its products.

This excellent book—now in its second edition and greatly enlarged—is described as "Edited by Ralph W. Kerr", and it is true that his co-authors have contributed a number of chapters, but it is largely the author's own work. In many parts, particularly those in which he is dealing with scientific aspects of the subject and in which his own investigations have contributed to what is known, the author writes critically, with a command of his subject and adequate familiarity with the work of others.

The book is in five sections, of which the first deals with the starch granule and the chief varieties of starch. Section 2, comprising five chapters, is concerned with the manufacture of various types of native and modified starches, the chapter on corn starch having been rewritten for this edition. Section 3 comprises two chapters on the physical properties (by Dexter French) and the chemical properties of starch, both critically written and including developments, almost up to the time of writing, in the synthesis of starch components.

Section 4 deals with reactions and includes chapters respectively on the hydrogen bond as a basis for interpreting certain starch properties and on dextrinization, both by G. V. Caesar, oxidation (by J. M. Newton and G. T. Peckham), the manufacture of dextrins and acid hydrolysis of starch, and a long one (by Ed. F. Degering) on derivatives, with more than three hundred references. Most of these chapters have been enlarged in the present edition and give clear evidence of the authors' practical experience of the matters under discussion. The amylases are excellently reviewed by E. Kneen, and modification of starch by enzymes treated by G. M. Severson. A chapter on miscellaneous reactions has been greatly enlarged in this edition to include new work on the interaction with iodine.

Section 5 comprises one chapter on the analysis of starch (this is a new chapter) and six on its uses in industry—for example, modern fermentation products (by L. M. Christensen), food, paper, textiles, adhesives (by A. Frieden) and miscellaneous uses. The chapter on starch in fermentation industries has been enlarged, while the practical, technical and commercial aspects are well treated in the various chapters on the uses and applications of starch.

There are pages of references to each chapter of the book, and complete author and subject indexes and numerous illustrations, both photographic and diagrammatic. The photographic illustrations are better finished than in the first edition. An error in many of the page headings in the chapters on the physical and chemical properties of starch reverses these titles. The book will be invaluable to the pure scientist and the technologist. R. H. Hopkins

THE ELECTRON MICROSCOPE IN METALLURGY

Metallurgical Applications of the Electron Microscope

A Symposium held at the Royal Institution, London, on 16 November 1949, and organized by the Institute of Metals in association with the Chemical Society, the Faraday Society, the Institute of Physics, the Institution of Electrical Engineers, the Iron and Steel Institute, the Physical Society, and the Royal Microscopical Society. (Institute of Metals Monograph and Report Series, No. 8.) Pp. vi+164+50 plates. (London: Institute of Metals, 1950.) 21s.

Magnifications beyond the range of the ordinary microscope are of metallurgical importance in many directions. Examples are to be found in the nature of the irresolvable constituents of hardened and tempered steels, the mechanism of age-hardening, the nature of the crystal boundaries and precipitations of ultra-microscopic films there. Further, the fundamental nature of plastic deformation, the real nature of slip bands, and the size of the fragments into which metallic crystals are broken down, all demand a technique beyond the range of normal microscopic vision.

Therefore, the symposium on the "Metallurgical Applications of the Electron Microscope", organized by the Institute of Metals in November 1949, in conjunction with a number of other societies interested in the same or similar problems, served to bring together a considerable mass of information regarding the potentialities of this instrument in the metallurgical field. The symposium was perhaps the more justified in that there has been, at any rate in some quarters, a feeling of disappointment at the progress so far made. The thirteen papers are now published by the Institute of Metals as Monograph No. 8, and cover the whole field, ferrous and non-ferrous, metal powders, heat treatment and mechanical working.

The widespread interest in the subject is exemplified by the fact that universities, research associations and industrial laboratories in Great Britain, United States, France and Germany have all contributed. To all those concerned, either from the fundamental or technological point of view, this collection of data is to be strongly recommended. Techniques for the production of replicas are discussed; and, although what the metallurgist would most like, namely, a direct picture of the metal surface, is unfortunately not yet available, the design and construction of a reflexion electron microscope may not be long delayed. F. C. T.

BRITAIN'S SCIENTIFIC SHRINES (5)

By ENG.-CAPT. EDGAR C. SMITH, O.B.E., R.N.

SCOTLAND

FOR carrying the survey of Britain's scientific shrines into Scotland, the plan adopted for the English counties is scarcely applicable, for some of Scotland's largest counties are the most sparsely populated, while for the greater part the homes and haunts and memorials, if not the birthplaces, of notable Scottish men of science are to be found in her university towns. The story of science in Scotland centres around her universities far more than is the case in England, and Scotland presents few parallels to the careers of such as Gilbert, Hales, Priestley, Jenner, Cavendish, Herschel, Dalton, Joule and Darwin. Some of England's most eminent men of science, owing to the religious tests, never entered Oxford or Cambridge, and were debarred from holding professorships in them. But in Scotland, with her educational traditions handed down from the days of John Knox, any student who could fend for himself on a meagre ration found the doors of the universities open, and, after the Reformation, the religious question seems to have shut them against very few. In attempting in a brief, and admittedly inadequate, sketch to recall to the reader some of those whose names are inscribed on the rolls of honour in science in Scotland, some part of the story of the universities must inevitably form the background.

Of the four Scottish universities, those of St. Andrews, Glasgow and Aberdeen came into existence before the Reformation, and that of Edinburgh just after; and their fortunes were affected not only by the struggles between Catholics and Protestants but also by the constant disputes between rulers, nobles, chieftains and clans, all of which were accompanied by much disorder. Recalling the circumstances, the impoverished state of the country, and the smallness of the population, it is not a little surprising that the universities managed to exist at all. In one of his many studies of the social history of Scotland, the Rev. H. G. Graham (1842–1906) said that even by 1650, after the Crowns of England and Scotland had been united, the total population of the country was only about 900,000, while the inhabitants of Glasgow numbered about 10,000, those of Aberdeen some 6,000, and those of St. Andrews a mere 1,500. One of Mr. Graham's essays was entitled "Glasgow University Life in Olden Times", in which he gave a striking picture of the hard and penurious life of both teachers and taught. Here, as elsewhere, the religious upheaval had its baneful effects on the young university, and with the coming of the Reformation, wrote Mr. Graham, "away fled Popish churchmen, students and masters, and when we see the august University once more all that is left of it consists of twelve individuals: a principal, three regents, four poor students, the principal's servant, an œconomus, a cook and a janitor. To such a miserable remnant are the functions and privileges left, with a meagre revenue of £25 yearly." From this deplorable state of things the University was rescued by the reformer and universal scholar, Andrew Melville (1545–1622?), who in 1574 at the age of twenty-nine, constituting the whole teaching staff in himself, lectured on Greek, Hebrew, Chaldee, Syriac, philosophy, physics, logic, rhetoric and chirology, and soon filled his rooms with students. In 1580 Melville returned to St. Andrews; but he had put the University of Glasgow on its feet again and by 1631 the half-ruined houses and tenements sheltering both professors and students were being replaced by the College in the High Street, which was destined to see the labours of a long line of distinguished men, including Adam Smith, Cullen, Black and their great successors, Thomas Graham, Rankine and Lord Kelvin. The ancient cathedral, in a part of which the University first met, still stands majestically at the top of the High Street, and at the foot of the hill the visitor can stroll through Glasgow Green, where on one Sunday afternoon in 1765 James Watt, pondering over the working of the University's model Newcomen engine, conceived the idea of a separate condenser. But all traces of the College which served the University for more than two centuries have been swept away, though some fragments of its masonry are incorporated in the Gatehouse at Gilmorehill.

With such a curriculum as that of Melville there was little room for mathematics; but it is worth noting that Melville's career coincided almost exactly with that of John Napier (1550–1617), who in the seclusion of Merchiston Castle, near Edinburgh, spent the greater part of his life in study and gave to the world his famous work on logarithms. He, like Melville, had studied at St. Andrews, and spent some time on the Continent, before marrying and settling down in his ancestral home. Ball says of him that "the business of his life was to show that the pope was anti-Christ but his favourite amusement the study of mathematics and science". It may be presumed that to-day no one reads Napier's commentary on the Apocalypse, but logarithms are in use all the world over. His famous book, "Mirifici Logarithmorum Canonis Descriptio", was published in 1614, and its tercentenary was the occasion of a notable commemoration by the Royal Society of Edinburgh, presided over by Lord Moulton, "a distinguished mathematician before he was a great lawyer". In his inaugural address, Lord Moulton said that though every fact known about Napier had become commonplace, it "left the man very imperfectly disclosed, but sufficed to show him strong and self-reliant, of solitary habits, of profound and untiring industry . . .", while "the invention of logarithms came on the world as a bolt from the blue. No previous work had led up to it, nothing had foreshadowed it or heralded its arrival. It stood isolated, breaking in upon human thought abruptly without borrowing from other workers or following known lines of thought." There were many other contributions to the tercentenary commemoration, which were all published in a special volume edited by Dr. C. G. Knott, a member of the staff of the University of Edinburgh, which was founded when Napier was engrossed in his studies at Merchiston Castle. Napier died on April 4, 1617, and was buried in the old church of St. Cuthbert. Among the memorials to him is his statue, which stands beside those of John Hunter, James Hutton, Sir Henry Raeburn and others in the Scottish National Portrait Gallery.

The next important figure in the history of science in Scotland is that of James Gregory (1638–75), who was educated in the University of Aberdeen and held the chair of mathematics first at St. Andrews and then at Edinburgh. The University of St. Andrews was founded in 1411 by Bishop Henry Wardlaw, that of Glasgow was founded in 1451 by Bishop Turnbull on a bull issued by Pope Nicolas V, a great patron of art and literature, while that of Aberdeen was founded in 1494 by Bishop William Elphinstone on a bull issued by Pope Alexander VI, who has been described as the most profligate prelate who ever sat on the apostolic throne. Whatever Alexander's misdeeds, Aberdeen benefited by his sanction for the establishment of its University, and it was not long before the present King's College was built, to be followed about a century later by Marischal College, founded in 1593 by George Keith, the Earl Marischal of Scotland. The present Marischal College dates only from 1906, when it was opened by King Edward VII.

Among those who were educated at King's College was Dr. Duncan Liddel (1561–1613), to whom Aberdeen owed its first chair of mathematics. A native of Aberdeen, Liddel spent the years 1579–1607 at various places in Germany, studying and teaching philosophy, medicine and mathematics, and making the acquaintance of Tycho Brahe. Returning home in 1607 with a comfortable fortune, he gave land to the University of Aberdeen and before his death made provision for founding a chair of mathematics at Marischal College. His death took place on December 17, 1613, and a memorial to him was placed in St. Nicolas Church. It was about forty years after Liddel's death that James Gregory became a student at Marischal College, and it was at Aberdeen he published his treatise on optics and invented the Gregorian form of reflecting telescope. He further increased his reputation by his visits to London and to Padua, and on June 11, 1663, was elected a Fellow of the Royal Society. Soon after this he was made professor of mathematics at St. Andrews, and in 1674 he was elected the first exclusively mathematical professor in the University of Edinburgh. His inaugural address was delivered in November 1674. Eleven months later, while showing his students the satellites of Jupiter, he was struck blind and died three days later at the age of thirty-six. He had, however, already done enough to give him a place among the immortals, and in 1938 both St. Andrews and Edinburgh joined in commemorating the tercentenary of his birth.

But James Gregory was only one of a remarkable family of men of science, members of which for two hundred years held professorships in one or other of the Scottish universities. They were the Bernoullis of Scotland. The founder of the family was David Gregory, minister of Drumoak, near Aberdeen, and from his two sons David (1627–1720) and James (1638–75) the dynasty descended. Science seems to have been in their blood, and one of them belonging to the sixth generation, Duncan Farquharson Gregory (1813–44), a Cambridge wrangler and the first editor of the *Cambridge Mathematical Journal*, appears to have been cast in the very same mould as his famous ancestor James. Omitting much that is of interest, a word or two should be said about the third David Gregory (1661–1708), one in a family of thirty-two children, because in 1683 he was elected to the chair previously held by his uncle; secondly, because he was the first in Edinburgh to teach the Newtonian philosophy; and thirdly, because he was the first Scottish mathematician to occupy a chair in an English university, being appointed in 1691 Savilian professor of astronomy at Oxford. That his influence was felt far outside Edinburgh is shown by Whiston, who in his memoirs said that in his own study of the "Principia" he was "greatly excited thereto by a paper of Dr. Gregory's when he was professor in Scotland wherein he had given the most prodigious commendations to that work, as not only right in all things, but in a manner the effect of a plainly divine genius, and had already caused several of his scholars to keep acts, as we call them, upon several branches of the Newtonian philosophy; while we at Cambridge, poor wretches, were ignominiously studying the fictitious hypotheses of the Cartesian, which Sir Isaac Newton had also himself done formerly . . .". Among Gregory's students who had "kept the acts" was John Keill (1671–1721), who accompanied his instructor to Oxford, opened at Hart Hall the first course of lectures in the new philosophy given in the University, and afterwards was given the Savilian chair of astronomy. In a previous article, mention has been made of David Gregory's monument at Maidenhead. His successor's tomb is in St. Mary's Church, Oxford.

The progress of scientific studies in Scotland in the seventeenth and eighteenth centuries and the outlook of her men of science were affected by many causes. With the union of the Crowns of England and Scotland in 1603 and the union of their Parliaments a century later, together with the diminution and disappearance of internal strife in both countries, came a loosening of the bonds between Scotland and France, and an increase in the intercourse between north and south of Britain with advantage to both. With London as the capital of the united kingdoms, it was only natural for the more adventurous to seek their fortunes in it, and from the early eighteenth century onwards Scottish men of science are found in ever increasing numbers taking their place in the scientific institutions of the capital. The very first president of the Royal Society was the Scotsman Sir Robert Moray, and among his successors in the eighteenth century were the Earl of Morton and Sir John Pringle. Pringle, like Moray, Watt, Telford, John Hunter, Baillie, Simpson, Lyell, Kelvin and Ramsay, is among the Scottish men of science buried or commemorated in Westminster Abbey.

It is generally admitted that in the eighteenth century the study of mathematics made little progress in England. It was much the same in Scotland, although in Colin Maclaurin (1698–1746) Scotland had one of the first mathematicians of the day, and his death in the Archbishop of York's Palace through illness brought on by his exertions in organizing the defences of Edinburgh against the Jacobites in 1745 was a very great loss. Maclaurin was much interested in astronomy, and had encouraged his pupil James Short (1710–68), the famous London telescope maker; but on the whole astronomy attracted few Scottish students. There was, however, much greater activity in the realms of chemistry and physics, which, like botany, were regarded as the handmaids of medicine, and were studied as such and not as separate sciences to be pursued for their own worth. Almost without exception, teachers in the Scottish universities possessed a medical degree, and it was as a great centre of medical education that Edinburgh became famous. On this matter there are many interesting notes in a paper by Mr. J. N. J. Hartley, entitled "The Early History of the Museum of the Royal College of Surgeons of Edinburgh", and published in the *Edinburgh Medical Journal* of 1948.

Mr. Hartley is the conservator of the museum housed in Surgeons' Hall, and in the course of his remarks he gives particulars of some of the many teachers and schools of medicine and anatomy, referring especially to the first Alexander Monro (1697–1767) or Alexander Monro "*Primus*", who was appointed in 1720 by the Town Council to be the first professor of anatomy in the University. Of this distinguished man, Sir Alexander Grant wrote: "he was not only the Father of the Edinburgh Medical School, but also the first professor of any kind who drew great attention to the University of Edinburgh from without and gave it the beginnings of its celebrity".

It was while Monro was thus adding to the reputation of Edinburgh that the University of Glasgow became almost as famous, partly through the work of William Cullen (1710–90) and Joseph Black (1728–99). A biography of Black was the last book written by Sir William Ramsay. In it is an illustration of the old College in the High Street, in which Black lived and worked, and reproductions of Kay's portraits of Cullen, Black, Adam Smith and James Hutton. Cullen was the first to teach chemistry at Glasgow as a separate subject, he was the first to lecture in the vernacular instead of Latin, and in 1755 at Glasgow he published his fruitful essay on "Cold produced by Evaporating Fluids". From 1746 onward the careers of Cullen and Black were linked together, for Black was Cullen's pupil and his successor in the chair of chemistry at Glasgow in 1756, and again in the chair of chemistry at Edinburgh ten years later.

Though Black lived to the age of seventy-one and came to be regarded as the Nestor of British chemists, his two great discoveries of the nature of 'fixed air' and the doctrine of latent heat were made while he was a young professor at Glasgow. Among other men of science associated with Glasgow in the eighteenth century were Dr. Robert Simson (1687–1768), professor of mathematics for nearly fifty years, whose "Elements of Euclid" formed the basis of numerous editions; John Anderson (1726–96), the somewhat litigious professor of natural philosophy, who sent a gun to Paris as evidence of his sympathy with the French Revolutionaries, and who by his will founded the famous Andersonian Institution, now incorporated in the Royal Technical College, Glasgow; Alexander Wilson (1714–86), who while engaged in typefounding became Glasgow's first professor of astronomy; Thomas Melvill (1726–53), the young divinity student who with Wilson recorded the temperature of the upper air by means of kites, and was the first to use a prism for examining the effect of introducing salts into the flame of burning spirits; John Robison (1739–1805), the close friend of Watt, who during 1774–1805 was professor of natural philosophy at Edinburgh; and William Irvine (1743–87), who held the chair of chemistry at Glasgow during 1770–87. In the story of Scotland's heritage of science, all these Glasgow worthies hold an honourable place.

Black's removal to Edinburgh occurred at a time when, in the words of Sir Archibald Geikie, "the Scottish capital had not yet begun seriously to suffer from the centripetal attractions of London. It was the social centre of Scotland, and retained within its walls most of the culture and intellect of that ancient kingdom." At Edinburgh, Black not only found his old master Cullen but also the philosopher Adam Ferguson (1723–1816), then professor of "pneumatics and moral philosophy", and Matthew Stewart (1717–85), the professor of mathematics. To Edinburgh in 1768 came the farmer–manufacturer–naturalist James Hutton (1726–97), to devote himself to scientific pursuits and to gain for himself a place among the giants of the heroic age of geology. These famous men were afterwards joined by John Playfair (1748–1819), preacher, writer, geologist and natural philosopher, who introduced the works of the French mathematicians into Scotland; Daniel Rutherford (1749–1819), the professor of botany who discovered nitrogen; and the wealthy landowner Sir James Hall, Bart. (1761–1832), of Dunglass, like Playfair an enthusiastic supporter of Hutton's views and himself the founder of experimental geology. In the whole range of science there were no more admirable characters than Hutton and Playfair. Of Hutton, Geikie wrote: "His character was distinguished by its transparent simplicity, its frank openness, its absence of all that was little or selfish, and its overflowing enthusiasm and vivacity"; while Dugald Stewart in his sketch of Playfair wrote: "Independently, in short, of his high attainments, Mr. Playfair was one of the most amiable and estimable of men: delightful in his manners, inflexible in his principles and generous in his affections, he had all that could charm in society or attach in private".

In Edinburgh in the eighteenth century, as elsewhere, there were clubs and convivial gatherings of writers, artists, lawyers and others, and it was from one of these, the Philosophical Club, formed in 1739, that sprang the Royal Society of Edinburgh, inaugurated in 1782, with John Robison as one of its secretaries. A few years before this, in 1776, Edinburgh had seen the laying of the foundation stone of the observatory on Calton Hill, which has in turn belonged to the City and to the Government and again to the City. It has seen many ups and downs, has often suffered from neglect—even as a Royal observatory—but after being reconditioned was taken over by the Astronomical Society of Edinburgh in 1938 and in October of that year was formally reopened by the late Sir James Jeans. Under the inspiring directorship of Mr. N. S. Matthew, it is now widely used for educational purposes.

Edinburgh's first official astronomer appears to have been the naval surgeon Dr. Robert Blair, who in 1783 was appointed professor of practical astronomy. His appointment came about in a very unusual manner. In 1782 Blair was serving in the West Indies in H.M.S. *Resolution*, in which on January 23, 1782, Captain Lord Robert Manners died of wounds received some months before. Now Manners was a son of the famous Marquess of Granby who had fought at Culloden, and a brother of Charles Manners, fourth Duke of Rutland, who was well known in government circles. Blair's devotion to his captain becoming known, the family, wrote Dr. John Doran in his "Memories of our Great Towns", "With generous alacrity importuned the Government to do something for him, and at their solicitation the Crown actually founded for Blair a Professorship of Practical Astronomy in the University of Edinburgh! The naval surgeon and physician had seen enough of the stars to know Orion's belt from Charles' Wain; but had he been ignorant of both it would not have much mattered, as the Astronomical Professorship was a sort of nominal office, without any charge. But if Dr. Blair was not a practical astronomer he was an experimental philosopher of great repute and his experiments and observations on the refrangibility of light excited considerable interest in his own day. . . ." Blair continued to hold his office until his death on December 22, 1829, at Westlock, Berwickshire. For a few years after this, the chair of astronomy remained vacant, but in 1834, shortly after his return home from South Africa, Thomas Henderson (1798–1844), the advocate's clerk who had risen to be the Astronomer Royal at the Cape, was appointed to it, and about the same time was given charge of the Calton Hill Observatory and made Scotland's first Astronomer Royal. Henderson's immediate successor was Charles Piazzi Smith (1819–1900), who was born at Naples and had the Italian astronomer Giuseppe Piazzi as his godfather, and he in turn was followed by Ralph Copeland (1837–1905), who superintended the building and equipment of the new Royal Observatory at Blackford Hill, made possible by the generosity of the Earl of Crawford.

Of greater importance to learning in Edinburgh than the erection of the Calton Hill Observatory was the building of the "New College of Edinburgh", the foundation stone of which was laid in the fateful year 1789. Unlike those of Glasgow, St. Andrews and Aberdeen, the University of Edinburgh owed nothing to bishops and popes, for its original college was opened by the Town Council and given university status by James VI, afterwards James I of England. Its constitution differed from those of the other universities, and in many matters, even in the appointment of professors, the Town Council held the control. This lasted until the University gained its independence by statute in 1858. The new College was not erected before it was needed, for its principal, the historian William Robertson, had written in 1768 that "a stranger when conducted to view the University of Edinburgh might, on seeing such courts and buildings, naturally enough imagine them to be almshouses for the reception of the poor . . ." ; while twenty years later, a writer in the *Scots Magazine* said that "the buildings of the University are in the same ruinous condition that they were in 1768 and the most celebrated University at present in Europe is the worst accommodated".

With the completion of the new College fresh faces appeared among the staff, and the lecture rooms became even more crowded. Black's death in 1799 had left open the way for his deputy, the botanical professor's son, Thomas Charles Hope (1766–1844), who had held the chair of chemistry at Glasgow and had learnt something of the new chemistry direct from the lips of Lavoisier and Berthollet. For forty-three years he lectured and experimented, and it is recorded that at one time his students numbered 575, while the total number who had listened to him was something like 16,800. There was nothing like this in the English universities. His famous colleague, John Leslie (1766–1832), who was born in the same year as Hope, had abandoned a career in the Church for science, had travelled on the Continent and in the United States and had become known for his experiments in radiation before succeeding Playfair in 1805 in the chair of mathematics, which he exchanged for that of natural philosophy in 1819. His first appointment, owing to something he had said about cause and effect, led to an unfortunate controversy, in the course of which Sir Joseph Banks, the president of the Royal Society, wrote to Leslie sympathising with him and adding : "Surely a man may fulfil his duty to his Creator without assenting unconditionally to every undigested tenet which our half-informed predecessors have left behind as a legacy to their more enlightened posterity. If it has pleased God to permit his creatures to increase in wisdom He will not condemn them for assenting to new opinions which their reason demonstrates to be just." Leslie was knighted at about the same time as Brewster, John Herschel and Charles Bell, and died on November 3, 1832. It was some time before the youthful James David Forbes (1809–68) was appointed to succeed him, and for a few months the natural philosophy lectures were given by John Scott Russell (1808–82), afterwards a famous naval architect. Another of the new professors was William Wallace (1768–1843), who held the chair of mathematics from 1819 until his retirement in 1838, when the Town Council paid Cambridge a compliment by choosing as his successor the Rev. Philip Kelland (1808–79), a Somerset curate's son who had been senior wrangler and first Smith's prizeman. Kelland proved unequalled as a teacher, and he died while president of the Royal Society of Edinburgh.

In such a sketch as this it would be only proper to include a mention of some of the famous Scottish inventors and engineers of the time, such as Watt, Telford and Rennie ; William Murdoch, Sir William Fairbairn and James Nasmyth ; Henry Bell and William Symington, the pioneers of the steam boat ; the Napier family of marine engineers and the Stevenson family of lighthouse builders, but space does not permit more. In view, however, of the approaching meeting of the British Association in Edinburgh, it is only appropriate to conclude by recalling the part played by Scottish men of science in its formation.

The story of the British Association was told in its official history published in 1921 ; but many more details are to be gleaned from such works as the "Home Life of Sir David Brewster" (1869), "The Life and Letters of James David Forbes" (1873) and other memoirs. It was Brewster and Forbes together with John Robison (1778–1843), the wealthy son of the natural philosopher, and the soldier-administrator-astronomer Sir Thomas Makdougall Brisbane, Bart. (1773–1860), who were prominent in founding the Association ; and they were among the Scottish contingent who, with their English and Irish supporters in September 1831, by coach or chaise, on horseback or foot, converged on York for the inaugural and epoch-making gathering. At York the founders received a warm welcome from the Yorkshire Philosophical Society, finding in the keeper of its Museum, John Phillips (1800–74), a most willing secretary ; in the Rev. William Vernon Harcourt (1789–1871) a far-sighted vice-president, and in his father, the Archbishop of York, a graceful host. From the Archbishop's Palace at Bishopthorpe, at one in the morning of September 30, after a lecture by Scoresby on magnetism, Brewster wrote that "the assemblage of beauty, fashion, and philosophy was really splendid . . .", while "the Archbishop has invited fifty or sixty of the philosophers to dine here to-morrow, among whom are Sir T. Brisbane, Thos. Allan and the rest of our Scotch party. . .".

In 1832 the newly formed Association met at Oxford and in 1833 at Cambridge ; and then, largely through Forbes, at Edinburgh with Sir Thomas Brisbane as president and Robison as local secretary. Some supporters had suggested Dublin, but Forbes would have none of this and wrote to Brisbane in 1833 : "It appears to me that it is little short of the duty of the Royal Society [of Edinburgh] to convey to the meeting of the British Association an invitation to make Edinburgh the place of their next meeting. . . . It has always been considered that the origin of the Society was in a great measure Scottish, and Sir D. Brewster, Mr. Robison and yourself have always been looked upon as its founders. . . ." A copy of this letter he sent to Sir Roderick Murchison, saying: 'My dear friend, you are a Scotsman, and though a deserter, you should not quite desert what is due to your country. Only look back and remember what Scotland did for the Association. . . ." Forbes had his way. The meeting was successful and he had the pleasure of entertaining Whewell, Peacock and Vernon Harcourt, of the last-named of whom he wrote, "I learn every year to look with more admiration and affection on that remarkable man". Brisbane, whose name is perpetuated by the capital of Queensland, it may be added, died at his birthplace, Brisbane House, Largs, at the age of eighty-six, and Brewster died at the same age at Allerly, Melrose, but Forbes died at Clifton at the age of fifty-nine. Forbes's grave is in the Dean Cemetery, Edinburgh, and that of Brewster in the grounds of Melrose Abbey.

RESEARCH IN OCEANOGRAPHY

THE sea, covering as its does three-quarters of the surface of the earth, presents unnumbered problems to whet intellectual curiosity and adventure, while economic and utilitarian motives for its scientific study are also pressing. Marine biology has always been actively pursued; in earlier days largely by amateurs and latterly by professionals at a number of well-equipped and well-staffed marine laboratories. Since zoology cannot be studied without regard for marine species, the universities of Britain have always fostered and, no doubt, always will foster, marine research on a considerable scale. Fewer botanists have found such interest in the plants of the sea. Economic stimulus has stimulated investigation of the shore seaweeds, and a research association now exists for this purpose alone.

Fundamental marine zoology has found its economic counterpart in fisheries research undertaken by the Laboratories at Lowestoft and Aberdeen, both full of vigour and ideas. These laboratories have had to study not only fish but also the food of fish and the waters which nourish and transport it. Study of the invertebrate fauna of the sea and the sea bed is in a healthy state; so is the physical and chemical study of the waters which fill the shallow seas frequented by fishing vessels. A re-deployment of effort is in progress; more hands would provide quicker results, but, in relation to the scientific man-power of the country, the staff available, especially in quality, is reasonable.

The Antarctic has become one of the best known of the major oceans by the tireless work of the Discovery Committee and its ships and staff, the contributions of which both to marine biology and to physical oceanography have been great. None the less, the motive for all their work has been economic —to provide a scientific foundation for the whaling industry. There have been huge fields of physical investigation which were neither proper for their study nor could they be undertaken with their limited staff. The entire expenses of the Discovery Committee have been met by the Government of the Falkland Islands from a cess levied on all whales processed in the Falklands or their territorial waters. Great Britain's contribution has been a negative one—revenue derived by taxation of the staff who live here.

Investigations to secure safer navigation hav always been and remain the concern of the Hydro grapher of the Navy. There was a time when th British Hydrographic Office unaided charted the sea of all the world. To-day the Admiralty's fleet o survey ships forms only a part of the survey fleet o the world, but the quality of its work ranks as hig as ever. Tidal investigations flourish both at th Admiralty and at the Liverpool Tidal Institute, th annual report* of which has just been published.

Theoretical investigations of much importance especially in hydrodynamics, have been made by few gifted free-lances in the universities, but physica oceanography has been ill organized. Apart fro nuclear physics, oceanography is probably the mos expensive of all scientific techniques, so that ther has been little opportunity for experimental physica investigation or for deep-sea research. Submarin geology and geophysics are in the hands of a fe men at a single university, who have had to borro ships when needed as best they could.

At a meeting of the Scientific Advisory Committe of the War Cabinet in January 1944, Vice-Admira Sir John Edgell, then Hydrographer of the Navy expressed the view that Great Britain, in its con tribution to research in oceanography, had falle seriously behind other countries, and suggested tha a British oceanographical institute should be set u without delay. Inquiry showed that there was considerable body of opinion in favour of concentrating the efforts upon physical studies, which ha been neglected as compared with marine biologica research. However, the Scientific Advisory Committee considered that the work of the propose institute should embrace both physical and biologica oceanography. In July 1946, the Colonial Offic raised the question of the future of the Discover Investigations. This matter was considered b various government departments interested and b the Advisory Council on Scientific Policy in conjunction with the earlier proposals, and as a resul the National Oceanographic Council and the Nationa Institute of Oceanography came into being (se *Nature*, March 17, p. 415). The steps leading to th formation of the Institute are indicated in its firs annual report†.

The National Institute, with Dr. G. E. R. Deaco as first director, has taken over the Oceanographi Group of the Royal Naval Scientific Service at th Admiralty Research Laboratory at Teddington, an also the Discovery Investigations, which had cease to be the responsibility of the Falkland Islan Dependencies on March 31, 1949; the Institute i also gradually taking over part of the work of th Oceanographical Branch of the Hydrographer of th Navy. The R.R.S. *Discovery II* and R.R.S. *Willia* *Scoresby* were purchased by the Admiralty from th Government of the Falkland Islands Dependenci and presented to the Institute. The shore work o the Institute remains dispersed among five establishments in the London area and one in Cornwall. Th very desirable concentration under the director i one place remains to be achieved.

Both the research vessels were under requisitio during the War, and their equipment in store wa destroyed by enemy action. Both ships have neede extensive refitting and re-equipment before resuming the Discovery Committee's programme in the southern hemisphere. R.R.S. *William Scoresby* was first to sea in January 1950 and proceeded to survey the Benguela Current off the coast of south-west Africa. It can be seen already that much information of first importance on the physics and chemistry of the current and on its faunistic content was obtained, and that the resources of the Institute will be strained to evaluate and publish the results in reasonable time. This ship also carried out fishing experiments in South African waters, some whale-marking and a considerable amount of work on the Agulhas Current before returning to England last autumn.

---

* Liverpool Observatory and Tidal Institute: Annual Report 1950. Pp. 16.

† Annual Report of the National Institute of Oceanography 1949-50. Pp. 48. (Cambridge: At the University Press, 1951.) 5s. net.

The larger R.R.S. *Discovery II* put to sea in May 1950 and proceeded to the southern hemisphere to undertake investigations on the lines of those between the Wars, but at seasons and in parts of Antarctic and Australasian waters previously least investigated. There was also a considerable number of other programmes for investigation. She is still at sea, but it is clear already that she will return prepared to add much to knowledge. The sea programme of the Discovery Committee will then have been completed. The working up of the vast faunistic collections must continue for many years. Similarly, the complete evaluation of the chemical and physical observations by the two ships at about four thousand stations during twenty years will require much effort.

The work on waves, swell, microseisms and currents initiated at the Admiralty Research Laboratory is being continued by the Institute. Although the main object of the wave research is to obtain quantitative information about the factors which influence the generation, propagation and decay of waves, such as will allow the wave conditions at any place to be predicted from wind charts and a knowledge of the local hydrography, the techniques which have been developed have immediate applications in places where meteorological information is not available. Such a possibility is being considered for Mauritius, where there is need of warning of the approach of a cyclone or heavy swell over the off-lying shoals used by local fishermen.

Modern oceanography demands larger ships, manned by officers and crew well versed in their specialized duties. The experience of the Discovery Committee, shared by the marine laboratories, is that it takes time to select and train such staffs and that it is a tragedy if key personnel have to be dispersed when a ship has to be laid up. But the larger ships have the capacity of collecting at a great rate. Even under the most favourable conditions, it will take a man ten weeks to work up observations which he can collect in one. Yet it would seem that the two vessels will have to be kept at sea and their collections and results appreciated, and the parallel laboratory investigations continued, by a staff of no more than sixteen scientific and six experimental officers. If these valuable, but expensive, ships are to be put to best use, a very considerable recruitment of staff would seem necessary.

In most fields of marine study the days of collecting for the sake of collecting are ended. The museums are stuffed with millions of specimens and station lists with hundreds of thousands of observations, woefully inadequate to give a true picture of the ocean it is true, but beyond the capacity of the systematists and physical oceanographers of Great Britain or, for that matter, of the world to work up. Support is more readily obtained for dispatching a spectacular expedition than for the quiet working up of the results afterwards or for their publication. An adequate theoretical background and due selection of problems for work at sea is now possible and can lead to great economy. There is no doubt but that the National Institute of Oceanography under its present director will seek to achieve this.

Cost of publication everywhere presents a grave problem often met by the compression of papers to the point of incomprehensibility. In chemistry the high reproducibility of experimental results and standardization of techniques may make possible compression intelligible to the initiated, but not so in oceanography. In the sea the same situation never repeats itself and, the cost of getting observations being what it is, each one has to carry all the interpretation it can bear. The cost of the many necessary illustrations is now very high, and it seems less easy to get the relatively small funds for publication than for the prosecution of the actual research. May one hope that the Institute will be able to maintain the high standard of presentation of Discovery Reports ?

Great Britain should be grateful that the creation of the National Institute of Oceanography has been courageously tackled and that investigations are proceeding on a wide front. It should get good value for the annual grant of £115,000 which departments of the home Government and certain Dominion Governments are providing. L. H. N. Cooper

BRITISH INSTRUMENT INDUSTRIES' EXHIBITION

The Exhibition of the British Instrument Industries, which took place during July 4–14, in the National Hall, Olympia, London, owed its inception to a suggestion made by the Department of Scientific and Industrial Research. Some two years ago, the Department put forward the suggestion that it might be helpful and instructive to industry if an exhibition could be staged at which equipment, covering the entire range of industrial instrumentation, could be displayed and its use demonstrated. This suggestion was put before a meeting of interested trade associations who, while accepting the Department's recommendation, felt that the scope of the Exhibition should be extended to include the products of the whole field of British instrument manufacture, covering every variety of the use of instruments. This wider conception provided the background of the Exhibition which has recently concluded, and the successful achievement of these aims has been an event of unusual significance in the long history of instrument-making in Great Britain.

There has been a tendency for instrument interests to become sectionalized, according to the broad uses of various classes of instruments, and the five participating trade associations (British Electrical and Allied Manufacturers' Association ; British Industrial Measuring and Control Apparatus Manufacturers' Association ; British Lampblown Scientific Glassware Manufacturers' Association ; Drawing Office Material Manufacturers' and Dealers' Association ; and the Scientific Instrument Manufacturers Association of Great Britain, Ltd.) have emerged as representing groups of manufacturers of instruments having certain specific fields of use, although the last-named association, S.I.M.A., covers instrument manufacture of great diversity. One reason for the special significance of the Exhibition is to be found in the fact that it involved a major co-operative effort on the part of these Associations, and demonstrated that the common ground of instrument manufacture is of sufficient extent both to permit co-operative effort and to render it highly desirable. The Exhibition has, therefore, served an excellent internal purpose, since it may well have checked a tendency for the total effort of instrument manufacture in Great Britain to be hampered by excessive emphasis being placed on sectional differences. There has, in the past, existed some confusion among the users of instruments in regard to methods of approach to the industry, and it is to be hoped that the common effort which has now been made may lead to a more unified system of access.

The Exhibition was also significant in its comprehensiveness. Previously, there have been displayed at various industrial exhibitions instruments peculiarly relevant to particular industries: a rather wider display of instruments has been staged at the British Industries' Fair; and in the very noteworthy exhibitions of the Physical Society the emphasis has been on instruments of immediate scientific interest. This most recent Exhibition of instruments, however, has given, for the first time, a complete picture of instrument manufacture in Great Britain, and has provided an opportunity of assessing the extent to which the extremely diverse and widespread requirements for instruments are being met by the range of products of the instrument industries. The display of instruments at Olympia gives solid grounds for the belief that instrument makers in Great Britain are, in general terms, adequately fulfilling their tasks, and that the diversity of requirements for instruments is being matched by an equal diversity and a commendable ingenuity of production.

Of the Exhibition itself it should be said that it was admirably staged. It was, naturally, a specialist exhibition, and it was not to be expected that the Hall would be thronged with people; one of the most pleasing features of the Exhibition was the genuine interest in instruments and their use which characterized almost every visitor. The area devoted to the exhibits was of an extent which allowed ample gangway space, and the lack of fatigue usually associated with a tour of an exhibition was quite exceptional. The organizing authorities are to be congratulated both on the general lay-out of the Exhibition and on the achievement of a very marked impression that this was indeed a display of very special products.

The diversity of instrument types is such that it would be impossible, and would serve no useful purpose, to give in any detail an account of the actual instruments which were displayed. A conspectus of modern instruments, such as that provided at Olympia, does emphasize the manner in which the use of instruments has been extended and entirely changed in emphasis during the past generation or two. It is not so long ago that Lord Kelvin devised electrical instruments specifically for use in the application of science rather than in the pursuit of fundamental knowledge. To-day, the majority of electrical instruments are designed to meet the requirements of the great electrical industry, and the need for precise electrical measurements in so many industrial and civil activities. Many visitors to the Exhibition must have remembered the time when such principles as those of thermo-electricity and hydrodynamics were little known and little used outside the curricula of universities. The control of all industrial processes to-day is dependent upon the concrete application of these and other principles in the form of instrument devices. The provision of complicated scientific glassware was, at one time, only achieved through the skill of individual glass workers here and there, who served, almost entirely, individual laboratories. From the display at Olympia it is apparent that scientific glassware of the utmost intricacy can be obtained by routine ordering through the appropriate section of the industry. Much of the time of the research worker used to be taken up in improvisation and the devising of particular apparatus necessary to the prosecution of his investigations. To-day, instruments are available which will fulfil practically every research need, and the days of almost complete dependence upon the laboratory workshop are largely a memory. In an entirely different field, the set-square, ruler and dividers have been supplemented by a whole series of drawing-office devices, and both the preparation and reproduction of drawings and blueprints have been revolutionized. It is realized to-day that full productivity is dependent upon the provision of the tools most appropriate to each field of endeavour, and it is equally apparent that effective activities in science, whether they be in the acquisition of new knowledge or in the application of knowledge to utilitarian purposes, require that there shall be available the requisite and appropriate instrumental aids. The Exhibition at Olympia has demonstrated that the range of such aids emanating from British instrument industries is most satisfactory in its comprehensiveness.

It must be obvious to any observer with an intimate knowledge of industry that the proportion of effort covered by research and development in the production of scientific instruments is abnormally high. There is frequently heard a complaint that a particular type of instrument with certain peculiar features is not available from any British manufacturer, whereas it can be obtained from some other country. It is, of course, equally true that in other countries the complaint is made that particular types of instrument with peculiar characteristics can only be obtained from Great Britain. While, superficially, it might appear to be desirable that every conceivable instrument or device should be produced by the instrument makers in Great Britain, yet it should be remembered that instrument-making is no more free from economic considerations than is any other industrial undertaking. There is much to be said for the view that it would, in fact, be a retrograde step if the instrument makers of every country attempted to produce every variety of instrument which can possibly be required by the scientific workers of that country, irrespective of considerations of the total universal demand for any one type. It is apparent that the instrument industries of Great Britain have attempted to meet, as completely as possible, the general requirements for instruments. Too often the magnitude of the achievement of the instrument maker is minimized through a sense of irritation caused by an inability to obtain from any maker an instrument exactly suited to a small but specialist use. It is very doubtful whether an extensive range of instruments, such as has been shown at Olympia, could have been made available had the instrument industries not been compelled, by economic necessity, to maintain a sense of proportion in their manufacture.

NEWS and VIEWS

Plant Industry in Australia: Dr. O. H. Frankel

Dr. O. H. Frankel has been appointed chief of the Division of Plant Industry, Commonwealth Scientific and Industrial Research Organization, Canberra. Dr. Frankel has had wide experience in the botanical field and has made outstanding contributions as a geneticist. He has been on the staff of the Department of Scientific and Industrial Research, New Zealand, since 1929. He was appointed first as a geneticist at the Wheat Research Institute, and later became chief executive officer of the Institute; more recently, he has been director of the Crop Research Division of the Department. A British subject by naturalization, Dr. Frankel was born in Vienna in 1900. He holds the degrees of doctor of agriculture of the University of Berlin, and master of agricultural science and doctor of science of the University of New Zealand. Dr. Frankel and his co-workers at the Wheat Research Institute have succeeded in breeding wheats which are suited to the unfavourable New Zealand environment and yet which combine the desirable properties of high yield and high quality. Thus New Zealand farmers can now grow wheats suitable for high-quality bread-making, whereas previously their wheats produced only low-grade biscuit flour.

Technical Personnel Committee

In a written answer to a question in the House of Commons on July 26, Mr. Alfred Robens, Minister of Labour and National Service, said that it has been decided to reconstitute the Technical Personnel Committee, which, under the chairmanship of Lord Hankey, dealt with questions of scientific and technical man-power during the Second World War and during the immediate post-war period.

The terms of reference of the Committee are: (1) To consider, make recommendations and deal with questions relating to the home and overseas demand for the available supply of scientific and technical personnel of professional or approximately professional standards, including the making of recommendations on its economic use and the need for increasing the available supply. (2) In connexion with the overseas demand for such personnel: (*a*) to make recommendations upon appropriate steps to promote the recruitment from the United Kingdom of persons required to assist the economic development of under-developed countries; (*b*) to consider any special steps which are required to provide opportunities for training in the United Kingdom of persons from under-developed countries. The Committee will be empowered to invite representatives from other Government departments or outside interests to be present when matters of concern to them are being discussed.

The membership of the reconstituted Committee is as follows: Chairman, Lord Hankey; members nominated by the Federation of British Industries, Sir Arthur Fleming, Sir Wallace Akers, and Captain A. M. Holbein; representative of the Universities, Sir Edward Appleton; chairman of the University Grants Committee, Sir Arthur Trueman; deputy chairman of the Advisory Council on Scientific Policy (nominated by the Lord President), Prof. S. Zuckerman; one representative each of the Treasury, Foreign Office, Colonial Office, Board of Trade, Commonwealth Relations Office, Ministry of Labour, Ministry of Supply, and Lord President's Office. The secretary will be Mr. A. J. S. James, Ministry of Labour and National Service.

Productivity of British Land

A Sub-Committee of the Research Committee of the Rural Reconstruction Association has published a report on "The land which would be required to produce the food requirements of Great Britain and Northern Ireland on the basis of present yields of crops and livestock". The Committee has taken the consumption of food in 1946 as a year when the diet was adequate and of which accurate estimates exist. By taking each of the main items in the diet it worked back to the land which would be required for total production, which was found to be 49,553,000 acres of crops and grass, whereas the total actually available is only 35,530,000, plus some nine million acres of rough grazing. It is thus concluded that Britain could feed herself if the average annual yield of crops could be increased by about 40 per cent. Alternatively, the calculations show that the target of the Ministry of Agriculture of 55 per cent home production of essential foods is modest. The report has very interesting appendixes on land requirements for poultry, cattle and pigs. The Committee in its calculations suggests that a much greater proportion of the meat requirements should be obtained from pigs and that if five million acres of cropland were devoted to production of pig foods the number could be increased to about 16 million, providing nearly 60 per cent of the estimated meat consumption. The report is one which deserves careful study.

Scottish Hill Farm Research Committee: First Report

The first report of the Scottish Hill Farm Research Committee of the Scottish Advisory Council has now been published (pp. 134+16 plates; Edinburgh and London: H.M. Stationery Office, 1951; 3*s*. 6*d*. net). Set up in 1945, this Committee was appointed to advise on the development and co-ordination of research in relation to technical problems of hill farming in Scotland. Three research farms have been established, each affording facilities for different types of investigation. At Sourhope, Roxburghshire, the management of grass hills is the dominating question; at Glensaugh, Kincardineshire, wintering problems are under consideration; and at Lephinmore, Argyll, the co-ordination of hill farming with forestry is being studied. The work carried out during 1945–49 is reviewed in detail. Among the interesting questions investigated is the possibility of applying fertilizers to hill land by means of aeroplane. Preliminary trials indicate that satisfactory distribution of lime can be effected in this way, but that reduction in costs is essential before the method can become an economic proposition. Problems concerned with sheep naturally form a major part of the agricultural research work in Scotland, and co-ordination of field trials regarding sheep-dips has been attained and a survey made of the breeding systems used in hill flocks. Various diseases cause unnecessary loss, and the Committee emphasizes the need for extension of the veterinary service. Special attention has been paid to heather. A review of the literature on the subject is included in the report, and recommendations made as to profitable lines of work to be undertaken with regard to this valuable plant. A new Committee to continue in office for a three-year period was set up in 1949. Among other activities, its programme will include economic studies and detailed surveys of the districts in which the three experimental farms are situated.

Reviews of Pure and Applied Chemistry

The first issue of *Reviews of Pure and Applied Chemistry*, published by the Royal Australian Chemical Institute, Melbourne (quarterly, £1 5s. a year), will be welcomed by chemists in Australia, but should prove of interest to a much wider circle of readers. The facilities for the publication of original researches in Australia are now quite well served by many journals, and the decision of the Institute to start a review journal is very sound. According to the opening editorial, the aim is to provide "a journal in which general articles and critical reviews in all branches of chemistry could be published". The contents of the first issue include a discussion of the mechanism of chemical change by Prof. F. G. Soper and an article dealing with the impact of chemistry on biology and medicine by Prof. A. R. Todd; the chemical engineering problems in the generation of nuclear power are outlined by Prof. J. P. Baxter, while Dr. K. L. Sutherland has reviewed the change of surface tension with time. Clearly the aims of this journal are different from those of either *Chemical Reviews* or *Quarterly Reviews*, since, if the first number reflects future policy, articles as well as detailed reviews receive equal prominence. Undoubtedly the more general articles, as well as the detailed reviews, will be welcomed by the members of the Institute, who vary from the pure research worker to the wholly administrative chemist. However, it should be appreciated that some articles are by no means as comprehensive or as detailed as those to be found in the two review journals quoted above. The editor rightly rejects any purely nationalistic objective in the inauguration of this journal; nevertheless, it is to be hoped that readers throughout the world will be able to look to it for periodical reviews of work in those branches of chemistry in which certain Australian schools are most active. The printing is good, and the diagrams are well reproduced. Within the limits which have been laid down, *Reviews of Pure and Applied Chemistry* has made a good start.

Bulletin of the Research Council of Israel

The *Bulletin of the Research Council of Israel*, the first number of which has recently been published (1, Nos. 1–2; pp. 168; March 1, 1951; Jerusalem; annual subscription (4 issues) £I 2; single copy 500 prutot, double number 750 prutot), is intended primarily to facilitate the publication of scientific papers dealing with problems of regional importance but of wider interest. In addition, preliminary communications on both fundamental and applied research will be accepted in the form of letters to the editor, and the present issue contains forty-one such letters. The nine papers included deal with such varied subjects as the geomorphogeny of Israel; long-range forecasts of rainfall; the formation of 'salt tables' in natural and artificial solar pans; the iodine number estimation of bitumen; the vegetation of the Kurkar Hills; egg-development and diapause in the Moroccan locust; estimation of the incidence and destructiveness of plant diseases (terminology and outline of the technique of visual appraisal); fractionation of whey proteins as a means of grading milk powders and detecting adulteration of fresh milk with milk powder; and investigations on *d*-limonene, a by-product of the citrus industry. It is intended in future to publish four numbers annually.

Bibliography of French Mathematics and Astronomy during 1940–48

The December 1950 issue (No. 6) of the *French Bibliographical Digest* (pp. 109; New York: Cultural Division of the French Embassy, 1950) lists the most significant books on mathematics and astronomy published in France during 1940–48, together with some works published in French by Belgian and Swiss men of science. Only works of at least university level are included; but special courses on higher mathematics given at French universities and college text-books of special interest are regarded as meeting this requirement. Some reviews which have been taken, with acknowledgment, from *Mathematical Reviews*, *Revue Générale des Sciences*, *Revue Scientifique* and the *Bulletin Critique du Livre Français* are included, and the books are listed alphabetically by authors' names in classified sections under mathematics and under astronomy. Prof. Arnaud Denjoy contributes an appreciation of French mathematics during the Second World War, and besides an index of authors and collective works there is a list of French periodicals dealing with these fields of science and a directory of publishers.

Bengal Immunity Research Institute, Calcutta

A pamphlet has been published by the Bengal Immunity Research Institute, Calcutta, on the occasion of its third anniversary on November 26, 1950, describing the origins and organization of the Institute. Research in medicine, chemistry, biochemistry, biology, physiology, bacteriology, therapeutics, materia medica, pharmacy and other subjects which bear upon the prevention, alleviation and cure of human diseases and disorders, is carried out. The Institute also seeks to develop new medicaments, to improve existing processes and products; it collaborates in the investigations on drugs at the Bengal Immunity Therapeutic Ward; and it organizes lectures and demonstrations. The research programme is scrutinized by a scientific advisory board. The number and character of the departments of the Institute are elastic: departments of bacteriology, biochemistry, chemistry and pharmaceutical chemistry and of pharmacology have been established, as well as a museum to accommodate specimens of Indian medicinal plants and their active principles, and a library containing more than six thousand volumes. The Institute has already published nearly five hundred papers.

Safety in the Laboratory

A manual on safety in the laboratory prepared by the Dunlop Rubber Co., Ltd., primarily for the guidance of its own technical staff, contains some excellent advice and information which will be found useful by all laboratory workers. It emphasizes that safety is largely a matter of exercising forethought and reasonable care. General safety policy, fire and first aid, and a safety code for laboratory practice are the headings of the three sections into which the manual is divided. An appendix deals with electrical procedure in laboratories. The safety code lists the various items and the appropriate precautions to be taken, as, for example, "Cathode ray tubes—wear eye-shields when handling cathode ray tubes in case of implosion", in alphabetical order. Messrs. Dunlop are to be congratulated on the way in which they have tackled the vital problem of safety in the laboratory and for making such excellent provision against laboratory and technical hazards.

Northampton Polytechnic

Dr. P. F. Soper, head of the Electrical Engineering Department of the Nottingham and District Technical College, has been appointed head of the Electrical Engineering Department of the Northampton Polytechnic, St. John Street, London, in succession to Dr. J. S. Tait, who has been appointed principal of the Woolwich Polytechnic. Mr. K. J. Hume, at present metrology superintendent of the De Havilland Engine Co., Ltd., has been appointed head of the National College of Horology and Instrument Technology (which is housed in the Northampton Polytechnic) in succession to Mr. R. A. Fell, who is returning to industry.

Medical Research Council : Travelling Awards

The Medical Research Council has made the following travelling awards for the academic year 1951–52 : Rockefeller Travelling Fellowships in Medicine : Mr. W. Burnett, surgical registrar, Professorial Unit, Aberdeen Royal Infirmary ; Dr. O. Garrod, outpatient registrar and medical tutor, Postgraduate Medical School of London ; Dr. J. N. Hunt, senior lecturer in physiology, Guy's Hospital Medical School, London ; Dr. G. C. Kennedy, temporary member of staff, National Institute for Medical Research, London ; Dr. B. P. Marmion, senior bacteriologist, Public Health Laboratory Service (at the Virus Reference Laboratory, Colindale) ; Mr. J. H. Peacock, lecturer in surgery, University of Bristol ; Dr. S. W. Stanbury, Junior Beit Memorial Research Fellow, Department of Medicine, University of Manchester ; Dr. E. M. Vaughan Williams, Schorstein Research Fellow in medical science, Department of Pharmacology, University of Oxford. Dorothy Temple Cross Research Travelling Fellowships in Tuberculosis : Mr. R. W. Baldwin, research assistant, Chemistry Department, University of Birmingham ; Dr. G. J. Cunningham, senior lecturer in morbid anatomy and histology, St. Bartholomew's Hospital Medical College, London. Travelling Scholarships in Medical Science (tenable in France under an exchange scheme with the Centre National de la Recherche Scientifique) : Mr. S. V. Boyden, Wellcome Fellow of the Animal Health Trust, Department of Animal Pathology, University of Cambridge ; Dr. J. L. Gowans, Medical Research Council research student, Sir William Dunn School of Pathology, University of Oxford.

Colonial Service : Recent Appointments

The following appointments in the Colonial Service have recently been announced : G. W. Lines (deputy director of agriculture, Sierra Leone), director of agriculture, Sierra Leone ; E. H. Probyn (assistant conservator of forests, Cyprus), senior assistant conservator of forests, Cyprus ; J. S. Smith (senior assistant conservator of forests, Cyprus), conservator of forests, Federation of Malaya ; J. H. Keast (senior surveyor, Nigeria), assistant director of survey, Nigeria ; R. N. Lissett (senior surveyor, Tanganyika), senior surveyor, Uganda ; T. W. Wignall (senior surveyor, Gold Coast), surveyor general, North Borneo ; J. S. Dunbar (draughtsman, Geological Survey Department, Tanganyika), chief draughtsman, Geological Survey Division, Tanganyika ; Miss L. M. Horne (woman nutrition officer, Trinidad), woman nutrition officer, Windward Islands ; M. J. Jacovides (forest assistant, Cyprus), assistant conservator of forests, Cyprus ; S. D. Watson (draughtsman, Lands and Mines Department, Tanganyika), chief draughtsman, Surveys and Town Planning Department, Tanganyika ; J. Heathcote, education officer (science), Kenya ; J. F. Cowie, veterinary officer, Uganda ; R. G. Erskine, veterinary officer, Nigeria ; G. A. Currie, statistician, East Africa High Commission ; W. J. England, principal, Egerton School of Agriculture, Kenya ; S. A. Granville, statistician, Statistics Department, East Africa High Commission ; A. M. Hobdey, temporary agricultural survey officer (cocoa), Gold Coast ; R. R. Philp, soil survey officer (temporary), Gold Coast ; P. D. Proud, fisheries officer, Aden ; S. A. Radwanski, soil survey officer (temporary), Gold Coast ; W. Rides, temporary agricultural survey officer (cocoa), Nigeria.

Announcements

The honorary degree of D.Sc. of the University of Oxford has been conferred on Dr. G. G. Simpson, of the American Museum of Natural History, New York.

The Royal College of Physicians has awarded the Weber–Parkes Prize to Dr. P. M. D'Arcy Hart, for his contributions to the epidemiology and prevention of tuberculosis ; and the Baly Medal to Prof. G. de Hevesy for his work on radioactive indicators and their application in biochemistry, animal physiology and pathology.

The Committee representing the Royal Society and the University of Sheffield has appointed Dr. B. A. Bilby as Sorby Research Fellow from October 1, to work in the Metallurgy Department of the University of Sheffield on martensitic transformation and deformation twinning in crystals. The Committee representing the Royal Society and the Armourers and Brasiers' Company has appointed Dr. A. J. Kennedy as Armourers and Brasiers' Company Research Fellow from October 1, to work at the Royal Institution of Great Britain on transient creep in polycrystalline metals.

The Royal Society has arranged a 'Sir Isaac Newton' Exhibition on the occasion of the Festival of Britain. The Exhibition will be held during August 13–31 from 11 a.m. to 4 p.m. (except on Saturdays and Sundays) in the Society's rooms, Burlington House, London, W.1. Admission will be free.

The Parsons Memorial Lecture for 1951 will be entitled "Sir Charles Parsons and Optical Engineering", and will be given by Mr. F. Twyman, in the Science Museum Lecture Theatre, on October 25, under the auspices of the Physical Society.

A conference on "The Chemistry and Physiology of the Nucleus" will be held at Brookhaven National Laboratory during August 15–17. This conference, which is being organized and sponsored by the Biology Department of the Laboratory, will include eighteen speakers and five demonstrations. It is hoped to publish invited papers. Inquiries should be addressed to the Biology Department, Brookhaven National Laboratory, Upton, L.I., New York.

THIRD WORLD PETROLEUM CONGRESS

WITH nearly three hundred papers from leading petroleum technologists in every oil-producing or oil-refining country, the Third World Petroleum Congress which met in The Hague during May 28–June 6 covered the whole range of the sciences concerned with the petroleum industry—geology, geophysics, engineering in all its branches and chemistry, as well as statistics, documentation and economics.

At least sixty sessions were held and all were well attended. In general, discussion was lively and to the point, being restricted only by the time factor, which was somewhat limited by the time taken to read in two languages the instructions regarding discussion.

Geology and Geophysics. In the session on the origin and migration of oil, when papers were presented by Margaretha Brongersma-Sanders (University of Leyden), by I. A. Breger and W. L. Whitehead (Massachusetts Institute of Technology), and by C. E. ZoBell (Scripps Institute of Oceanography), the consensus of opinion was that there is need for generally accepted definitions and methods of analysis of organic matter occurring in geological formations. This is particularly true for crude oils in relation to migration and classification studies, but also applies to maltha, asphalt, asphaltic, pyrobitumen, etc. The setting up of a committee to study these matters was recommended, and it was suggested that it should consist of Prof. V. C. Illing (United Kingdom), M. Louis (France), G. R. Schultze (Germany), H. M. Smith (United States), and K. van Nes (The Netherlands). It was also resolved that the Permanent Council of the World Petroleum Congress take the initiative in clarifying the terms relating to oil migration.

Several papers on palæontology and sedimentology were discussed in two sessions, an important contribution being that of T. F. Grimsdale, who proposed geological correlation on a world-wide scale. In comparing Venezuelan and Middle East rock sequences of the Tertiary, Mr. Grimsdale uses pelagic (open ocean) foraminifera. From this subsection of the geological section came two resolutions. The first, based on a paper by D. J. Doeglas, stressed the desirability of regional investigations into sedimentary deposits and environments, as proposed in Project 5 of the American Association of Petroleum Geologists; but such studies should not be limited to the Gulf Coast area. The second resolution recorded the opinion that world-wide correlations could be established in the Upper Cretaceous and in the Tertiary formations by means of the pelagic foraminifera.

Regional geology of oilfield areas was the subject of several papers, a session with four papers on the Middle East being concerned mainly with Persia. There were also sessions on Italy, with seven papers, and on Mexico.

In the subsection on geophysics, there were nine papers dealing with seismological, gravitational, and electrical methods.

Drilling and Production. In this section there were about fifty papers covering all aspects of this important branch of the industry. In the session on drilling technique, the papers were mainly devoted to mechanical processes associated with the drilling of oil wells. Two resolutions concerned the standard testing of casing centralizers, and a proposal that the American Petroleum Institute consider standard specifications for integral-joint casing.

Opening the session on drilling, completion and production technique, the chairman pointed out that the papers clearly showed how technique has advanced since the early days of the industry. For several of the papers a considerable mathematical background was necessary.

Discussion on the type of mud used in completing oil wells demonstrated that oil-well performance could be materially improved by choice of the proper drilling fluid. The general opinion was that oil-base muds are equal or superior to oil-in-water emulsion muds, or to normal clay–water muds for well completions, but that water alone is probably the best fluid as far as drilling speed is concerned.

The value of laboratory investigations for the development and improvement of drilling and production technique was evident in the discussion on several papers. Investigations into the properties of the cements used in deep wells were reported in a paper from the Institut Français du Pétrole, and it was recommended that blast furnace slag cements should be used for the purpose. Work on the effect of particle size on the physical properties of drilling mud makes it possible to predict the viscosity of a clay-base fluid for a given concentration of solids, provided particle-size distribution is known.

A new approach to the knowledge of the behaviour of crude oil emulsions was outlined in a paper on a universal size-frequency distribution law for emulsion particles. When water and oil are produced together, their separation causes difficulties in practice. A formula has been derived statistically for describing droplet size distribution and has proved its value also in other oil-industry operations.

The importance of additional recovery from oilfields was pointed out in several papers, and methods of secondary recovery were reviewed. There were also several reports of laboratory investigations. It was also stated that in Digboi notable increases in production-rates have been obtained by washing waxy wells with kerosine. The effect is to soften, rather than to dissolve, wax in and near the well.

Physical Refining Processes. In this section an interesting discussion on calculations in relation to distillation apparatus and information was given from the Polytechnic Institute of Brooklyn of a new laboratory apparatus for the determination of equilibrium flash curves of complex mixtures. This apparatus is a modified type of recirculating equilibrium still, is compact, of low initial cost, and is expected to provide an improved basis for calculations.

Chemical Refining Processes. The session on hydrogenation and hydrocarbon synthesis was attended by a large audience, and discussion centred mainly on the development of synthesis. It seems that vapour-phase processes are likely to receive competition from the liquid-phase processes now being developed. Although fluid-catalyst technique is largely applied in the vapour-phase processes, the fixed-bed process still received much attention. An improved large fixed-bed plant is shortly to come into operation in Germany.

The development in Germany of the one-stage process for destructive hydrogenation of crude oil to gasoline with new catalysts occupied most of the discussion as regards hydrogenation. Combined hydrogenation and catalytic or thermal cracking processes are likely to be used on a large scale in Germany.

In the session on catalytic reforming, an interesting paper was that by E. V. Murphree on a fluid hydroforming process, which is claimed to produce gasoline of improved octane rating. The fluid-process plant was said to cost 40 per cent less than fixed-bed units.

A paper on a new process for the polymerization of gaseous olefins to motor gasoline gave rise to interesting comparisons with the well-established solid phosphoric acid process.

The importance of sulphur removal and recovery from petroleum products was reflected in the five papers in the session on chemical treating processes. Methods for sulphur removal ranged from conventional soda sweetening of gasoline to hydrofining —selective hydrogenation of sulphur compounds. The latter process has attractive prospects.

Petroleum Chemicals. This section was concerned with the properties and the application of petroleum-based chemicals. Thus, in the detergent session, the five papers related to the extraordinary growth of petroleum detergents in the United States, where such materials now account for 55 per cent of the total American production of synthetic detergents. It was clear that the market outside the United States cannot be forecast from American developments, and it appeared that although the alkyl aryl sulphonates lead in the detergent field, alkyl sulphates, when prepared from petroleum, are likely to challenge their position. The influence on detergent properties of the hydrocarbon constitution was specially discussed.

In regard to biocides, it was stated that our knowledge of the chemical and physical compositions of mineral oils is still insufficient to guarantee that a certain oil would be suitable for agricultural use without previous field testing.

Composition of Petroleum. During the discussion of a group of papers on pure hydrocarbons, attention was directed to the fact that international exchange of data on these materials could be improved. It was therefore recommended that the extension of such exchange of research data should be explored. The discussion dealt mainly with the suitability of different criteria for determining hydrocarbon purity, and with the applicability of various physical constants for identifying and analysing hydrocarbons.

Properties of crude oils were considered from two aspects: first, the classification and evaluation of crude oils; and secondly, their commercial evaluation. It was considered that characterizing factors now used do not correlate with chemical composition but mainly summarize the physical properties. It would be convenient, although it did not appear possible, to combine the two aspects into one simple factor. It was concluded that knowledge of the chemical composition of crude oils necessitates a more complicated scheme of analysis, which would require more uniformity in methods of investigation in order to correlate results obtained all over the world.

Ten papers in this section were devoted to various aspects of the constitution of petroleum. The investigation of the complex mixtures of which petroleum fractions are composed has been simplified by modern methods of group analyses. In regard to determination of oil composition by spectrographic analysis, it was considered that the emphasis should be more on so-called type analyses.

Utilization. Papers in this section dealt with the utilization of such petroleum products as engine fuels, lubricants, heating fuels and bitumen.

In the session on gasoline engine fuels, the reduction of engine friction was suggested as an alternative to higher compression ratios in order to reduce fuel consumption. It was also pointed out that there is room for improvement in automatic control of spark advance. In the overall economic picture, increased cost of high-compression engines should be weighed against increased cost of producing higher anti-knock gasoline.

The gas turbine fuel session discussed three aspects of the general subject. First to be considered was the complicated position which exists because the severe cold-test requirement of aircraft turbine fuel specifications limits the supply sources. Opinions varied widely as to the extent to which engine and fuel should contribute to the solution of the problem. Secondly, on the use of boiler-type fuels in stationary and marine gas turbines, the economics are not favourable without a cheap fuel. Difficulties due to varying percentages and composition of ash from the fuel are still serious. Finally, the Pescara system as applied to locomotives was dealt with. In this system a free-piston diesel is combined with a turbine, through which it develops its power and which functions simultaneously as a variable-torque transmission element.

Four papers on motor lubricants all dealt with some aspect of additives; the general comment was that the large amount of research being carried out is insufficiently stressed. It was also suggested that viscosity-index improvers may not be effective at high rates of shear, the effect of pressure not having been investigated. Industrial and special lubricants and electrical oils were also discussed.

Construction Materials. This section dealt mainly with materials, construction, equipment and corrosion. One interesting proposal made by two French authors is for a method of heat exchange whereby the two fluids are in direct contact. It was stated that it is effective where there is no danger of emulsions being formed due to the nature of the oil or of the cooling water.

Miscellaneous. Sections 9 and 10 dealt respectively with transport, storage and distribution of petroleum products, and with economics, statistics, documentation, education and training.

HUMAN PROBLEMS OF THE SCOTTISH HIGHLANDS

In an article in a recent issue of the *American Scientist* (39, No. 2; April 1951), Dr. Fraser Darling discusses recent concepts of human ecology. Human ecology, he suggests, deals with the structure of animal communities which man dominates and their development through the ecological principles of succession. With Paul Sears he believes that "the social function of ecology is to provide a scientific basis whereby man may shape the environment and his relations to it as he expresses himself in and through his culture patterns". To-day it would not be wise to set up human ecology as an exact science but rather to say that human problems may be nearer solution if they are tackled ecologically. Human ecology and social science can be good science but should not be confused with social service, as is so often done.

Dr. Fraser Darling also considers whether there is any difference between human ecology and social anthropology. If there is any difference between them, he suggests, it is that human ecology deals essentially with process, and the value of the ecologist in society will be in his power and accuracy in elucidating causes and forecasting consequences.

The West Highlands of Scotland, for example, may serve to illustrate the ecological approach to the study of behaviour. In the Highlands there is a very old and, in many ways, primitive human culture existing in an administratively awkward and physically refractory terrain set on the fringe of a highly industrialized urban civilization. Highlanders have been part and parcel of the national structure of Britain for only two hundred years, having until then lived a different kind of life in standards, laws, language and techniques from the rest of Britain. Yet Highlanders are not New Hebrideans or Eskimos over whom British people, try as they may to the contrary, feel some kind of mental superiority. The Highlanders are a race of people of probably greater average intelligence and intellect than the rest of the British community though indistinguishable from it in physical appearance. As members of this race moved so smoothly and successfully in the 'dominant' civilization, it was overlooked how different was the inner rhythm of life and the style of thought and tradition. The new centralized British government of that day merely extended its administrative, economic and social regime to include the Highlands, and with some ameliorations and some encrustations this applies to-day.

In human ecology, too, history can never be neglected; a cross-sectional social survey is not ecological unless it studies origins and successions or, in other words, process. The significance of political action as an environmental factor must also be remembered. The manipulation of the salt tax, for example, in the last part of the eighteenth and early nineteenth centuries had profound results on the lives of Highlanders, and the transposition of the English system of poor relief had amazing consequences. Again, the island of Islay was immune from spirit duty in the late eighteenth century, distillers flocked in, the bread corn of the people was deflected to whisky, the distillers were soon making money advances (at their own rates) on the barley crops of small tenants, and drunkenness was rife and the people were reduced to an appalling social state. The detailed research into population movement conducted by the West Highland Survey shows that this island has suffered more than any other part of the Highlands from excessive emigration.

Another historical factor at the root of the Highland problem to-day is the exploitation which natural resources suffered in the past. Among these was the cutting down of forests to supply wood for ship-building and iron making. The destruction of the forests meant the removal of cover, and this environmental factor is of great importance in human lives. Lack of cover imposes various social problems in certain kinds of urban communities, and in the Highlands has imposed a set of conventions almost the exact opposite of our own. Darkness is the only cover; but this is supplemented by a build-up of psychological cover. The Tiree crofter visits the Duke of Argyll's factor on the nights of no moon, though he could just as well go in the day. A man and a girl in the Hebrides will ignore each other in daytime should they meet on the road; but he will be calling at her home just about the time of night when in our culture we should have taken our leave. Good manners require that he be gone before it is light.

The ultimate disappearance of the forest was followed by the introduction of sheep farming on the extensive extractive system in the second half of the eighteenth century. The immediate social consequences of this were unfortunate in that the people were pushed to the coast and suffered a forcible social break. In other parts the sheep–cattle ratio is grossly disturbed and conditions for the peasantry become desperate. In the Highlands it is now possible to gauge the social health of the people by knowledge of the sheep–cattle ratio in an area. If the ratio is wide, 30–50 or more sheep to one cattle-beast, there are grave social problems; if it is less than ten, there are few. The sheep–cattle ratio can also be correlated with the age-structure of the population. It is children who keep milk-cows on the land and when the population grows old, as it did in Assynt in 1931, the number of milk-cows goes down.

Nor should the human ecologist forget the diet of the people he is studying. The introduction of the potato in the West Highlands has raised many social problems caused by an increase in the population and a fall in the standard of living.

The attempt to study social and economic problems apart from the ecological background is bound to cause difficulties. Yet, contrary to biological principles, politicians have recently decided to give a substantial subsidy to hill ewes in Scotland. This idea may have worked well in the Southern Uplands of Scotland but in the poor terrain of the Highlands might have been specially designed for further deterioration of the habitat and for fostering social unhealth.

Depopulation and deterioration of the age-structure go together, but they bring a new set of social problems. People in and out of the Highlands have said often that industries should be established there, industries of the kind where wheels go round in an important way. But what has happened? Where such industry has been established, there has been even greater depopulation in the adjacent rural areas; yet the big problem is how to maintain dispersion. Fort William and Kinlochleven may have provided Britain with aluminium; but they have created new social problems and solved none.

In small communities problems of human ecology arising from depopulation and deterioration of the age-structure are manifold. In the first place, the old remain in power and so prevail that they can initiate an era of reaction in the life of a community; so that in a region of strict Presbyterianism, all gaiety for the young is frowned upon and nowhere do the young show greater consideration for the old than in the Highlands. There are many townships where there are but few married couples. Brothers and sisters have cared for their old folk, and now that they are gone they continue living in their parents' houses and cannot bring themselves to the considerable upset of getting married. The social urge and necessary gaiety are not there. This depression of the vivid social life of man is likely to lead to such undesirable consequences as burning of the hills in an excitement bordering on hysteria.

Religion is also a considerable ecological factor; but it must always be related with other environmental characteristics. In the Highlands a small remote community with poor services might have much more chance of survival if it were Catholic than if it were free Presbyterian; there is a greater sense of freedom in the old liberal and almost Columban style of Catholicism. Dr. Darling also suggests that, despite the fact that tradition and accumulated experience are part of man's environment, and for all the importance of the physical and biological factors, the ethos is still the biggest ecological factor of all in the life of the individual.

MECHANISM OF RESISTANCE TO INSECTICIDE IN HOUSEFLIES

By Dr. J. R. BUSVINE

London School of Hygiene and Tropical Medicine

LABORATORY tests have revealed interesting differences in the type of tolerance of two strains of insecticide-resistant housefly. The strains investigated were:

Italian Resistant Strain. Following one of the earliest observations[1] of DDT-resistant houseflies, a laboratory colony was started at the Istituto Superiore di Sanita in Rome. A sub-colony was kindly sent to us in 1948 and has been cultured at the London School of Hygiene and Tropical Medicine since, with occasional selection for resistance to DDT[2], but no other insecticide.

Sardinian Resistant Strain. During 1947–50 there was widespread house-spraying with residual insecticides in Sardinia, in connexion with a campaign for the eradication of Anophelines[3]. Flies were observed to have become resistant to 'Chlordane' and gamma benzene hexachloride, as well as to DDT. In October 1950 Mr. J. F. Newman brought to England a colony of these flies and kindly let me have a sub-culture.

Normal (Rome) Flies. A colony started from normally susceptible flies in Rome before wide use of DDT, sent to us in 1948 and maintained here since.

The flies were reared and tested in rooms kept at 27° C. Two methods were used to assess resistance:

(1) *Application Test.* Minute drops (0·4 $mm.^3$) of insecticides dissolved in mineral oil were applied to individual flies, narcotized with carbon dioxide, by an 'Agla' micro-injection apparatus. Median lethal concentrations were estimated graphically from probit/log concentration curves based on 24-hr. kills.

(2) *Knock-down Test.* Observations were made of the rate of knock-down of flies in a 500-ml. beaker treated with acetone solution of DDT to leave a residue of 0·01 mgm. per sq. cm.[4].

Resistance to DDT

Effect of solvent used. Mineral oil was used in application tests rather than acetone (which has been used by other investigators) because of the difficulty of dealing with minute drops of a highly volatile solvent. Some comparative tests with oil and acetone showed how greatly this small point of technique affects the degree of resistance recorded (Table 1).

Table 1

	Median lethal dose (micrograms per fly) Normal flies	Median lethal dose (micrograms per fly) Sardinian flies	Ratio Sardinian/normal
DDT in oil	0·44	7·2	16
DDT in acetone	0·12	36	300

The results obtained with acetone are in line with those of other investigators who have recorded resistance ratios of several hundred to one; but the oil solution results seem more reliable for the following reasons.

The thorax of a treated fly remains covered with a film of oil, forming a primary toxic phase which, by the partition law, saturates all phases (tissues) in the proportion of the original solution. Internal depletion by metabolism could be made good from this reservoir. Losses of the film, by contacts of the fly with the cage, should be equal at all doses, since the volume applied is constant. After application in acetone, the solvent evaporates in a few seconds, leaving supersaturated liquid; this crystallizes out in an hour or so, leaving tiny scales and blobs of DDT crystals at higher doses. As there is no oil film, the cuticle wax of the insect must form the primary phase. There is very little of this, so it is easily saturated, and this saturates other tissues with DDT; therefore, the toxic action on susceptible flies is greater than with oil applications. The resistant flies, however, are able to metabolize the DDT (see below) and deplete the small reservoir in the cuticle wax. The relatively large crystals aggregated on the outside are an inefficient means of maintaining the saturation of the wax, apart from the fact that they may be dislodged by the movements of the fly. This accounts for the higher doses needed to kill the resistant flies.

Speed of 'knock-down' by DDT. In tests in which DDT was applied to the thorax, flies of the Italian and Sardinian strains were about equally resistant to DDT; but in the beaker tests there was a very marked difference, as shown by the results in Table 2.

Table 2

	Normal Rome strain		Italian strain		Sardinian strain	
	Males	Females	Males	Females	Males	Females
Percentage down in 20 min.	86	35	7	0	69	27
Percentage down in 40 min.	100	93	24	11	93	80
Percentage dead after 24 hr.	100	100	19	8	30	11

The Sardinian flies are almost as rapidly paralysed by the DDT as the normal strain, but most of them recover if removed from the surface after 40 min. The Italian flies, as shown by Harrison[5], are highly resistant to the paralysing effect.

Toxicity of DDT after injection. The relative resistance of the three strains of fly to DDT (in oil) was very similar if the insecticide was injected into the thorax instead of being applied to the outside. The median lethal concentrations obtained were about half those in application tests, thus: Rome 0·06 per cent; Italian 1·0 per cent; Sardinian 0·9 per cent. The paralysing effect of DDT was exhibited earlier by the Sardinian flies than the Italian ones, after injection as well as after application of the poison, though the final kills were about the same.

Table 3. Median lethal concentrations of DDT analogues for three strains of housefly compared with rates of dehydrochlorination *in vitro* (according to Cristol, ref. 5)

Compound	Median lethal concentration			Ratio of M.L.C.s III/I	Dehydrochlorination (lit./sec./mol.)
	Rome I	Italian II	Sardinian III		
Bromine-DDT	0·15	2·1	1·9	13	3,470
pp′ DDT	0·11	1·7	1·8	16	2,480
DDD	0·22	1·65	1·85	8·4	568
op′ DDT	1·3	13·5	4·1	3·2	37
Dimethyl diphenyl trichlor-methane	0·36	7·1	0·75	2·1	11
'Methoxy-chlor'	0·12	1·25	0·27	2 3	10

These observations suggest that the difference in rate of action of DDT on flies of the two strains cannot be explained by differences in rate of penetration of the cuticle.

Resistance to DDT analogues. The relative toxicities of a selection of DDT analogues to the two resistant strains of flies were made by application tests. In Table 3 the results are compared with the ease of dehydrochlorination, *in vitro*, according to Cristol[5]. It will be observed that those compounds which readily split off hydrogen chloride and leave the non-insecticidal ethylenic compound are tolerated by both strains: but the analogues which are more stable in this respect are relatively toxic to the Sardinian strain. Fig. 1 shows that the relative resistance of the Sardinian strain, as compared with the normal (Rome) strain, is roughly proportional to the logarithm of the rate of dehydrochlorination.

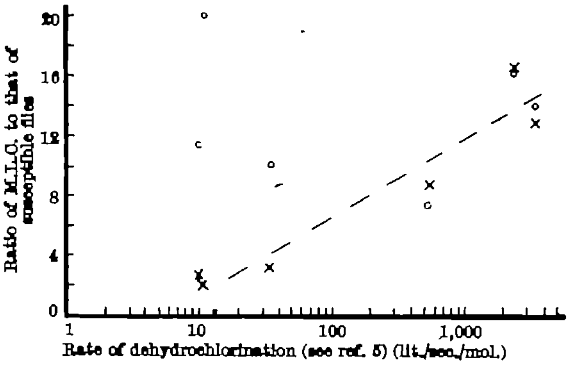

Fig. 1. Relation between resistance to various DDT analogues and their rate of dehydrochlorination (*in vitro*). Resistance is indicated by ratios of the median lethal concentrations for Italian (○) and Sardinian (×) flies to corresponding doses for normal (Rome) flies

Resistance to a Range of Insecticides

The degrees of increased resistance of the two resistant strains, as compared with normally susceptible flies, is shown in Fig. 2 and Table 4 for a range of insecticides. The following points may be noted.

(1) The Italian strain is distinctly resistant to DDT and to pyrethrins, but towards the other insecticides it is as susceptible as the normal (Rome) strain.

The moderate, but quite definite, resistance to pyrethrins is surprising and inexplicable. Houseflies which have so far developed resistance to insecticide in the field have only become tolerant of synthetic, chlorinated hydrocarbon insecticides; that they are capable of becoming resistant to pyrethrins may be of considerable practical importance.

Table 4. Median lethal concentrations of various insecticides, for two insecticide-resistant strains of housefly, compared with a susceptible strain from Rome

Insecticide	Median lethal concentrations			Ratios of M.L.C.'s to Rome strain	
	Rome (Normal)	Italian	Sardinian	Italian	Sardinian
DDT	0·11	1·7	1·8	15·5	16·5
Chlordane	0·04	0 038	2·8	0·95	70
Dieldrin	0·006	0·007	0·3	1·2	50
Aldrin	0·009	0·010	0·3	1·1	33
Gamma BHC	0·006	0·005	0·05	0·85	8·5
Toxaphene	0·09	0·09	0·90	1·0	10
'Lethane'	0·60	0·65	0·70	1·1	1·2
'Thanite'	0·80	0·90	0·85	1·1	1·1
Pyrethrins	0·07	0·35	0·06	5·0	0·86

(2) The Sardinian strain is about as resistant to DDT as the Italian strain. In addition, it is highly resistant to chlordane and several other chlorinated hydrocarbon insecticides. The resistance to chlordane is not surprising, in view of the wide use of this insecticide in Sardinia, but dieldrin and aldrin and toxaphene have not been used there. The two first are allied to chlordane in chemical constitution, but toxaphene is not very similar.

Discussion

It is difficult to imagine any single hypothesis which could explain the curious differences in the resistance of the Italian and Sardinian strains. Previous investigators have shown that resistant houseflies are able to break down DDT to a non-toxic compound by dehydrochlorination[6-8]. The data illustrated by Fig. 1 might suggest that the two strains owe their resistance to dehydrochlorination mechanisms with different specific actions; that of the Italian strain being more efficient in dealing with those DDT analogues most difficult to hydrolyse *in*

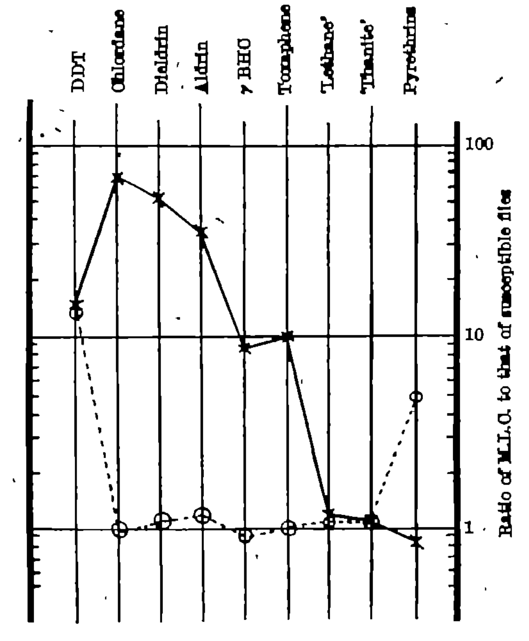

Fig. 2. Degrees of enhanced resistance to various insecticides shown by two strains of housefly. Resistance is indicated by ratios of the median lethal concentrations for Italian (○) and Sardinian (×) flies to corresponding doses for normal (Rome) flies (Logarithmic scale for convenience)

vitro. However, it is the Sardinian strain which is more efficient in resisting other chlorinated hydrocarbon insecticides, including dieldrin and aldrin, which are difficult to hydrolyse (if we are to judge from results *in vitro*). Furthermore, the resistance of the Italian strain to the early knock-down by DDT cannot be related to a more rapid dehydrochlorination, for Wintringham[8], who worked with this strain, found that it metabolized DDT very slowly (only 23 per cent in 5 hr.).

As earlier writers have suggested, the dehydrochlorination mechanism does not fully account for DDT resistance, and one is driven to postulate an additional defence mechanism. This would partially explain my results, assuming that the unknown mechanism predominates in the Italian strain, while the Sardinian strain relies mainly on dehydrochlorination.

CARNEGIE INSTITUTION OF WASHINGTON

ANNUAL REPORT FOR 1949-50

THE annual report for 1949–50 of the Carnegie Institution of Washington* includes the report of the president of the Institution, Dr. Vannevar Bush, as well as those of the executive committee and the auditors, and also the yearly record of departmental activities and co-operative studies.

The feature of the president's report is the discussion of the nature of research, and especially the methodology of the basic scientific research with which the Institution is primarily concerned. This is defined as the effort to extend, for its own sake, our grasp of the workings of Nature and of man, while applied research seeks to produce a new and useful device, material or process by capitalizing the growing body of fundamental knowledge. In both types of research there are two general approaches. One is to improve the tools, including the use of mathematical analysis, and usually proceeding by refinement, painstaking examination of sources of error and by testing of available materials. In the second a concerted attack is made upon a specific problem, applying all possible methods and instruments, and creating new ones for the purpose. Dr. Bush points out that even the objective centralized attack often turns the investigator into unexpected paths, and it is essential to keep in mind the true relation between the man of science and the instruments he uses. These are aids, not objects, and are important only as they foster the creative activity of the investigating mind. What distinguishes the really great man of science is the ability to sense or discern those places where truly great significance lies and where the tools available can open up a really wide crack in the wall of the unknown. More than forty years of experience has justified Andrew Carnegie's conviction that an institution which sought out the unusual scientific worker and made it possible for him to create to the utmost would be worth while.

Reviewing the research activities of the year, Dr. Bush refers to the publication during the year by Dr. R. E. Wilson and Dr. A. H. Joy of the radial velocities of 2,111 stars, thus essentially completing a programme begun by the Mount Wilson Observatory in 1910 which has yielded velocities of about 14,000 stars of all spectral types. During the year the 200-in. Hale telescope and the 48-in. Schmidt camera took their place with the 100-in. and 60-in. telescopes on Mount Wilson on the regular observing schedules of the Observatories. On June 26, 1949, Dr W. Baade with the 48-in Schmidt camera discovered the trail of a very unusual asteroid which has now been found to possess the shortest period (409 days) of any known asteroid and comet and has been named Icarus.

At the Geophysical Laboratory of the Institution careful measurements on about three hundred specimens of quartz have shown easily measurable differences in the behaviour of crystals from granite and those believed to have been formed in the later stages of igneous activity. Measurements on the effect of pressure on the inversion-point of quartz indicate that at the maximum pressure reached—corresponding to a depth of twenty-miles below the surface of the earth—the inversion-point is raised by more than 200° C. Further work on the feldspars has yielded quantitative information on their co-existence and stability, and the conditions of temperature and pressure under which they have been formed. Measurements on the melting of silicates in the presence of water under pressure have also continued, and the high-pressure steam filter autoclave has been further developed. Studies, in co-operation with the Department of Terrestrial Magnetism, of the earth's crust using waves produced by large explosions resulted in agreement that the velocity of earthquake waves is 5·9–6·0 km./sec. and also, reducing our estimate of the thickness of the upper layer, bring into agreement the shear-wave arrival times for near earthquakes. The same Department has continued its measurements of the residual-magnetism properties of sedimentary rocks, and studies on the direction of easiest magnetization indicate that these directional magnetic properties had their origin when the rocks were laid down as sediments. A great increase of cosmic rays coincident with a great solar flare was again observed; these high-energy radiations appear to be a nucleonic component of cosmic rays coming to the earth from the vicinity of the sun, and the observed particles are not mesons. The study of proton–proton scattering has continued, and, as a result of biophysical studies using radioactive tracers on the effect of inorganic ions on cellular activity, the ability of organisms to concentrate potassium from their environment can be interpreted in terms of the formation of relatively stable potassium compounds within the cell.

Investigations on photosynthesis, in the Division of Plant Biology, have been concentrated primarily on the photochemical part of the reaction by which the light absorbed by the various chloroplast pigments is converted into chemical energy. It has been found that the fluorescence spectra of red algæ do not match the summations of the fluorescence spectra of their purified pigments, although the different pigments do function to some extent independently. A highly fluorescent pigment, present in the cells which surround the so-called guard cells controlling the openings through which gases enter the leaves of certain species of vetch, possesses a fluorescence spectra resembling those of certain types of porphyrins. A mutant of *Chlorella* has been found which contains chlorophyll, but is incapable of reducing carbon dioxide, although it can evolve oxygen when illuminated. Chloroplast experiments have shown that the reactivation by precipitation of disintegrated chloroplast material depends primarily upon the physical state of the precipitate, and similar results have been obtained by treatment with various salts, by increased acidity, and by very low concentrations of streptomycin, which combines specifically with the chloroplast material. Methods have been worked out for separating uronides from leaves, and it appears possible that the great variations, independent of photosynthesis or respiration, of sugar concentration in leaves, may be associated with a reversible formation of uronides, which ties up the sugars. The principles controlling the evolution of plants have been studied by examining the growth of contrasting climatic races under varied temperatures in controlled greenhouses at the California Institute of Technology. The *Poa* grasses included with hybrids of *Achillea* and *Mimulus* in these studies were also used in studies of the influence of environment on chromosomal pairing.

* Carnegie Institution of Washington. Year-Book No. 49, July 1, 1949–June 30, 1950, with Administrative Reports through December 15, 1950. Pp. xxxvi+220+7 plates. (Washington, D.C., 1950.) 1 dollar.

In the Department of Embryology of the Carnegie Institution one of the chief advances on the anatomical side has been the achievement of sex reversal of the gonad in the opossum by experimental treatment in the embryonic stage with the female sex-hormone œstrogen. A detailed study of the embryonic development of the external muscles of the human eyeball was being prepared for publication, and studies on the developing brain and liver, with respect to chemical factors in the synthetic activities which characterize fœtal growth, indicate that specific chemical changes can be correlated with changes in the form of the developing nerve cells as seen under the microscope. The investigation on the physiology of the uterus has led to the development of the multi-channel tokodynamometer, by which obstetricians can record the contraction of all parts of the human uterus in childbirth and distinguish normal patterns of contraction from abnormal types which do not permit smooth and properly timed passage of the infant. Studies of the action of drugs upon the uterus were being continued, and an investigation of the biochemistry of uterine muscle in relation to the functional states of the reproductive system has shown that the presence of an effective amount of actomyosin in the uterus depends upon the ovarian sex hormone or œstrogen.

TEA RESEARCH INSTITUTE OF EAST AFRICA

A NEW research institute concerned with problems bearing on the cultivation and manufacture of tea has been inaugurated at Kericho, Kenya Colony, to serve tea producers in the three East African territories. Well-equipped laboratories have been built and a nucleus staff is in residence. At present the activities of the Institute are divided between a general agricultural department, covering agronomic and pathological problems, and a chemical department concerned with soils and plant biochemistry.

The funds for the support of the Institute are provided by the territorial Tea Boards of Kenya, Tanganyika and Uganda, which were recently established by legislative ordinances for the regulation of tea production, marketing and export.

Following the example of the British Grassland Research Station, the Institute has been incorporated as a company limited by guarantee without share capital, in Kenya, thus obviating the necessity for parallel legislative action in three territories of different constitutional status.

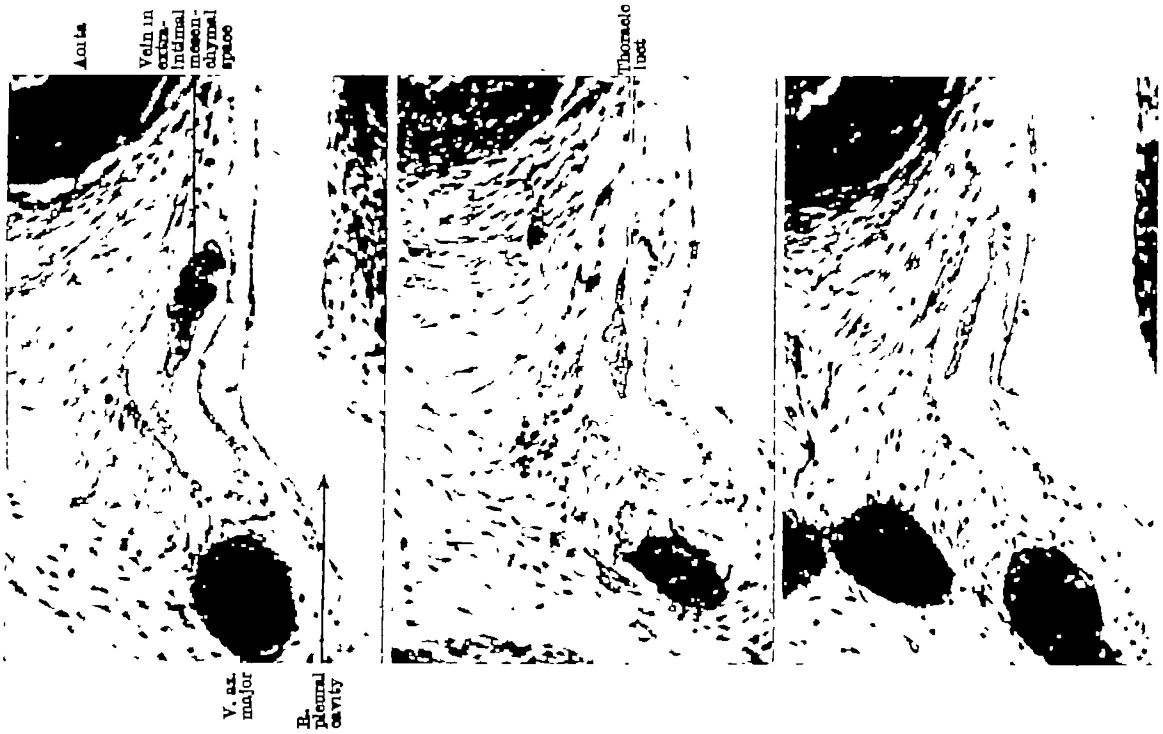
The governing body consists of ten members, six of whom (two from each territory) are nominated by the Tea Boards to represent producers, the remaining four being the directors of agriculture in the territories and the director of the East African Agriculture and Forestry Research Organization. The latter, Dr. B. A. Keen, has been elected chairman. During the preliminary stages of establishment, pending the working out of a constitution, the affairs of the Institute were sponsored by Messrs. Brooke Bond and Co., Ltd. On this account buildings and development generally were able to proceed without delay.

The tea industry in East Africa is relatively young and dates back about twenty-five years. The approximate acreage of mature tea in East Africa is 33,000, with a production of 19,000,000 lb. in 1950. East Africa has contracted out of the international agreement for restriction, and production is expanding. The immediate problems for a research institute are therefore largely concerned with soil and fertility conservation, establishment of young tea and the improvement of types of tea by selection.

DEVELOPMENT OF THE MAMMALIAN LYMPHATIC SYSTEM

By N. K. BALANKURA
Anatomy School, Cambridge

THE problem of the development of the lymphatic system in the mammal still remains unsettled. Sabin[1] regards the lymphatic vessels as direct derivatives of the embryonic veins. The lymphatic vessels make their first appearance at the four centres of radiation in relation to limb girdles. By the process of continuous and uninterrupted sprouting they extend centrifugally and invade almost the entire body. Lewis[2] believes that the lymphatic vessels are formed by the confluence of multiple venous outgrowths. These venous derivatives have previously become detached from the main venous channels and later they transfer *in toto* to the lymphatic system. Huntington[3], Huntington and McClure[4] and Kampmeier[5] have shown that the systemic lymphatic vessels are formed by fusion of the perivenous mesenchymal spaces. These spaces develop as separate lymphatic anlagen outside the intima of the early venous channels. They do not communicate directly with the veins except at definite points in the lymphatico-venous connexions which are secondarily formed. The connecting segments between the veins at the root of the neck and the proper systemic lymphatic vessels are provided by the paired jugular lymph sacs.



Three stages of degeneration in one of the right ventromedial tributaries of the azygos vein engulfed within the developing thoracic duct

The present investigation has been made into the development of the lymphatic system in the sheep and man. The findings confirm in the main the view advocated by Huntington, McClure and Kampmeier. Developmentally, the thoracic duct seems to consist of two separate components. The terminal part is formed by direct venous outgrowths forming the jugular lymph sac. The greater part (systemic lymphatics), on the other hand, arises *in situ* by the confluence of a system of mesenchymal spaces which in the majority of cases develops in close association with the degenerating veins. Therefore, the endothelium lining the greater part of the thoracic duct is derived from the undifferentiated mesenchymal cells, which never served previously as the lining of the venous channels. This is in sharp contrast with the development of the jugular lymph sac. The sac merely serves as a link between the great veins at the root of the neck and the rest of the proper systemic lymphatics; thus only the terminal parts of the thoracic duct and the right lymphatic duct are directly derived from the embryonic veins.

Three different stages can be recognized in the process of the formation of the systemic part of the thoracic duct: hæmal, transitional and lymphatic. The development proceeds in the cranio-caudal direction and different stages may overlap each other. In the hæmal stage venules and venous capillaries (venolymphatics of Kampmeier) are laid down along almost the entire distance eventually occupied by the thoracic duct. These venous capillaries possess two main functions: to drain the blood back towards the heart and to absorb the tissue fluid. During the transitional stage, these small veins become detached from the main venous channel and can no longer fulfil their previous functions. Thus the tissue fluid and the lymph which drains towards them accumulate to form cavities in the mesenchyme outside the lumina of the detached veins. The isolated cavities are known as the extra-intimal or perivenous mesenchymal spaces. They are in actual fact the primordia of the lymphatic channel. In the lymphatic stage the extra-intimal mesenchymal spaces become enlarged and coalesce with each other mainly in the cranio-caudal direction, thus giving rise to the continuity of the main lymphatic channel. The detached veins under the pressure of the expanding mesenchymal spaces degenerate and finally collapse and merge into the surrounding tissue.

In the 29–30 mm. stage human embryo, though the continuity of the thoracic duct from the innominate vein at the root of the neck to the first lumbar vertebra has been established, the detached veins in various stages of degeneration can still be observed, as shown in the accompanying three illustrations.

During the course of investigation, the posterior lymph sacs, the retro-peritoneal lymph sac and the mesenteric lymph sac were not demonstrated satisfactorily as direct derivatives of veins. The existence of these sacs must be regarded as doubtful. As in the case of the greater part of the thoracic duct, the cisterna chyli develops from the confluence of the extra-intimal spaces. However, it differs from the other systemic lymphatics only by the more extensive coalescence of the mesenchymal spaces and their subsequent enlargement. [March 22.

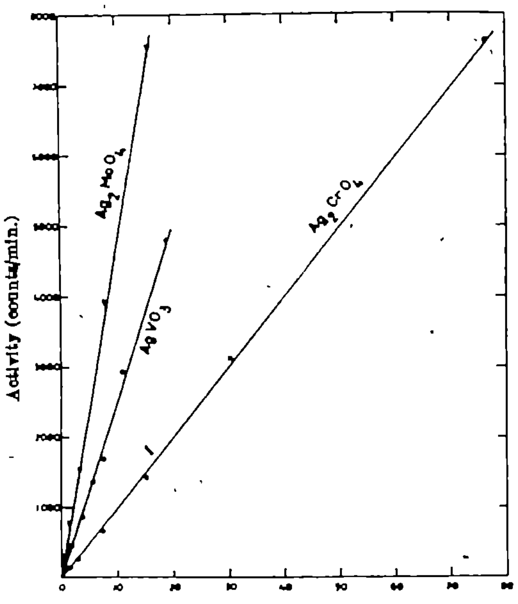
Radiochemical Determination of Chromium, Vanadium and Molybdenum by means of Radioactive Silver

THE extreme sensitivity of measurements of radioisotopes makes it possible to use the artificial radioelements as an aid in analytical chemistry. In our experiments we have used radioactive silver for making quantitative estimations of small amounts of chromium, vanadium or molybdenum present, in steel or in various substances. Insoluble silver salts can be prepared by means of these elements. Previous investigations have shown that all these silver compounds are suitable for radioactive measurements, except silver vanadate, which gives no reproducible results. Therefore, we dissolve the silver metavanadate in boiling 50 per cent nitric acid, and silver is precipitated as chloride; the latter is filtered on a fritted glass filter, so giving directly a radioactive sample for counting. A Geiger–Müller tube (*R.C.L.* Chicago) with thin mica window is used for the radioactivity measurements.

Radioactive silver, $^{110}_{47}Ag$ (supplied by the Isotope Division, Atomic Energy Research Establishment, Harwell), is dissolved in nitric acid, and the solution is evaporated to dryness on a water-bath. A neutral solution of radioactive silver nitrate is prepared; and by means of this solution chromium is precipitated as silver chromate[1], vanadium as silver vanadate[2] and molybdenum as silver molybdate[3]. As shown in the accompanying graph, standard curves are obtained when the activities of the precipitate are plotted against the corresponding amount of metal used. From these curves, unknown concentrations of chromium, vanadium or molybdenum can easily be determined if the same experimental and geometrical conditions are reproduced.



Mgm. of molybdenum, vanadium or chromium

Less than 1 mgm. of metal can be determined. However, a solution of radioactive silver nitrate with very much higher specific activity can be used, and eventually the smallest amount of metal detectable is limited by the solubility product. This radiochemical method is very quick, accurate and also convenient, because the same radioactive indicator is used for the chemical determination of different elements.

One of us (C. B.) wishes to thank Prof. G. Guében for the opportunity of working in the Institute of Nuclear Studies, Liège.

Structures of Uranium

Dickins, Douglas and Taylor[1] have recently pointed out that the tetragonal structure for β-uranium, proposed by Tucker[2] on the basis of the room-temperature X-ray examination of a quenched uranium – chromium alloy containing 1·4 atomic per cent chromium, is essentially the same as that of the σ-phase, which is of such great technical importance. Kasper, Decker and Belanger[3] have obtained similar results.

We have been engaged for some time in the X-ray examination of uranium at high temperatures and have succeeded in obtaining satisfactory powder photographs of β- and γ-uranium, using filings sealed off in an evacuated silica capillary tube. Attempts made to index the β-photographs by the method described by Ito[4] had led to a monoclinic unit cell containing 30 atoms and having the dimensions $a = 9{\cdot}99$ A., $b = 7{\cdot}85$ A., $c = 8{\cdot}67$ A. and $\beta = 101° 42'$; but comparison of these photographs with those of a 1·4 atomic per cent chromium – uranium alloy quenched from 720° C. showed that there was a very strong resemblance, although obviously the unit-cell dimensions of the two substances differed considerably.

Detailed analysis showed that all the lines of the β-uranium photograph could be explained with a tetragonal unit cell containing 30 atoms and having the dimensions shown in the accompanying table, with the exception of two very faint lines. Several small-angle reflexions, occurring only as spots on photographs of stationary specimens, were also explained more satisfactorily by the monoclinic than by the tetragonal unit cell; but there was no unequivocal evidence that the tetragonal structure is not essentially correct. However, there are marked discrepancies between the calculated and observed intensities which show, as Tucker himself says, that much more work is necessary before the final structure of the uranium – chromium alloy can be elucidated. More significant, perhaps, are the intensity differences observed between β-uranium and the uranium – chromium alloy, which show that the two structures, although based on the same theme, are not identical, and make it clear that the detailed structure of β-uranium will have to be worked out from X-ray observations on the element itself and not on the chromium alloy. (*Note added in proof:* X-ray photographs of the uranium–chromium alloy taken at 720° C. have confirmed these intensity differences.)

There is one feature of this alloy which may be of interest, although not strictly relevant in the present context; and that is its behaviour on filing. Filings prepared for X-ray examination gave only the α-uranium pattern if examined before re-heating to 720° C. and quenching. After the latter treatment, however, the σ-pattern was re-established.

The accompanying table gives the unit-cell dimensions and theoretical density for β-uranium and the uranium – chromium alloy as well as for the body-centred cubic unit cell of γ-uranium, together with previously reported values; and includes also the corresponding figures for α-uranium based on Jacob and Warren's results[5], taking into account that their dimensions almost certainly refer to kX. and not to angstrom units, and that they used a value of $0 \cdot 606 \times 10^{-24}$ for Avogadro's constant instead of $0 \cdot 6024 \times 10^{-24}$, the currently accepted value.

UNIT-CELL DIMENSIONS AND DENSITY

	α–U (room temp.)	β–U (720° C.)	γ–U (805° C.)	U–Cr (1·4%) (room temp.)
a (in A.)	2·858	10·759 ± 0·001	3·524 ± 0·002	10·590 ± 0·001
b (in A.)	5·877	—	—	—
c (in A.)	4·955	5·656 ± 0·001	—	5·634 ± 0·001
Density	19·00	18·11	18·06	18·56

PREVIOUSLY REPORTED VALUES

	α–U	β–U	γ–U	U–Cr
a (in A.)	2·852		3·49 (at 800° C.)	10·52
b (in A.)	5·865		—	—
c (in A.)	4·945	None	—	5·57
Density	18·97		18·6	19·02
Ref.	5		6	2

It will be seen that the unit-cell dimensions for the 1·4 atomic per cent chromium alloy are not the same as those reported by Tucker. The precise significance of this is not clear at the moment, but it may be noted that metallographic examination reveals no sign of segregation in the alloy, the composition of which (1·35–1·40 atomic per cent chromium) is not seriously different from that of Tucker's. An estimate of the density of such an alloy, of uncertain value perhaps, may be worked out from measurements of the bulk thermal expansion of uranium[7] in the β-range, extrapolating to room temperature and making an allowance for the effect of the chromium. The value so obtained is 18·8, which is intermediate between Tucker's value and that given by the present work.

It will also be noticed that the figures obtained for γ-uranium differ somewhat from those previously published. Density considerations suggest, however, that they are of the right order, the density at 800° C., calculated from measurements of bulk thermal expansion, being 17·8. A value of 18·6, as given by Wilson and Rundle's results, would therefore seem to be unreasonably high.

This note is published by permission of the Director of the Atomic Energy Research Establishment, and it is hoped to publish fuller details elsewhere. The uranium – chromium alloy was prepared, and the chemical analysis carried out, by the Metallurgy Division of this Establishment.

Errors in Determination of Specific Activity and Turnover Rates of Radioactive Isotopes

In experiments designed to investigate the turnover rate of certain organophosphates by the use of phosphorus-32, a serious error has been detected in the results obtained by the use of conventional techniques.

For the determination of the radioactivity of the inorganic phosphate fraction of a trichloracetic acid extract of tissue, the phosphate is generally precipitated as a magnesium ammonium salt and counted as such. It is also customary to add unlabelled phosphate to serve as carrier and so ensure complete precipitation of the phosphorus-32. In order to avoid the loss of time due to the necessity for allowing the solution from which phosphorus-32 is being precipitated to stand several hours, we investigated the possibility of applying the method for the determination of inorganic phosphate described by Ennor and Stocken[1]. If it was possible to extract the inorganic phosphate from the aqueous phase with *iso*butanol in 10 sec. as has been reported, we believed that the phosphorus-32 content could be determined by counting the alcohol phase in a conventional liquid counter of 10 ml. volume. Preliminary experiments using a model system containing sodium dihydrogen phosphate, some of which was labelled, have indicated that not only can the phosphorus-32 be extracted quantitatively in 10 sec., but also that the counts obtained by this method agree with those obtained by counting the precipitate of magnesium ammonium phosphate.

When, however, a similar comparison is carried out on a trichloracetic acid extract of a liver from an animal injected with material labelled with phosphorus-32 two hours before death, divergent results are obtained.

From the results of the model experiment, it was expected that the counts in the magnesium precipitate would equal those in the *iso*butanol extraction of the trichloracetic acid extract. It is clear, however (see table), that the precipitate has many more counts. In both the examples cited, an extraction of the precipitate with *iso*butanol gives results practically identical with the extraction of the trichloracetic acid extract. This result is taken to indicate the presence of a compound containing phosphorus-32 which does not react with molybdate to form a phosphomolybdate complex, and so remains insoluble in *iso*butanol. This conclusion is strengthened by the fact that after wet-ashing in sulphuric and nitric acids, butanol

Magnesium precipitates were counted by means of a *GM*4 end-window counter and were mounted on disks of filter paper. All *iso*butanol extracts were counted in an *M*6 *GM* liquid counter having a capacity of 10 ml. All determinations were carried out in duplicate and counts were taken over such a period as to reduce the statistical error to 1–2 per cent. All counts are expressed in terms of the end-window counter

	Counts/min /ml. of extract	
	Exp. 1	Exp. 2
Magnesium ppt.	850	1,540
*iso*Butanol extraction of ppt.	560	1,240
,, ,, ,, trichloracetic acid extract	540	1,280
,, ,, ,, ashed ppt.	900	1,540
Specific activity (based on ppt.)	8·1	10·0
,, ,, (based on *isobut.* extraction of trichloracetic acid extract)	5·3	8·1

extraction now gives the same number of counts as did the precipitate.

The error which appears as a result of differences between the counts in the *iso*butanol and in the precipitate is reflected in the specific activities, as indicated in the accompanying table.

The question now arises as to the nature of the contaminant, and preliminary experiments indicate that the adenosine polyphosphates are co-precipitated as, in fact, has been noted by Lehninger[2]. It has also been established that the degree of co-precipitation is dependent upon the amount of carrier phosphorus which has been added.

The preliminary results indicate that the long-accepted method for determination of the radioactivity of inorganic phosphate is subject to considerable error and, therefore, that the conclusions that have been drawn in the past on the turnover rate, etc., of an organophosphate are also subject to error. Experiments are now in progress to determine the magnitude of this error. It has also been established that the method described by Ennor and Stocken[1] is suitable for the determination of both phosphorus-31 and -32, and that it is free from error. A full report of the work will be submitted for publication elsewhere.

A Particulate Impurity Found in Solutions of Radioactive Phosphorus

Experiments involving the use of radioactive phosphorus (phosphorus-32) incorporated into nucleoproteins have indicated that samples of nominally carrier-free radioactive orthophosphate contained, at various times during 1950, an appreciable proportion of activity associated with particulate matter. Recent samples of phosphorus-32 have, however, been free from this impurity. This impurity is of serious consequence when measurements of the radioactivity of proteins labelled with phosphorus-32 are to be made, as the impurity is carried down on protein precipitates, where it remains in spite of repeated washing.

	Total counts per min.	Percentage activity in precipitate	Phosphorus (μgm.)	Specific activity (counts per min. per μgm. phosphorus)	Ratio of spec. activities of precipitate to supernatant
Supernatant 1	196,000	—	858	228	—
Supernatant 2	198,000	—	900	222	—
Precipitate 1	10,800	5·5	3·9	2,700	11·8
Precipitate 2	7·8	0·004	4·5	1·74	0·008

The nature of this impurity has been investigated and a method for removing it from solutions of radioactive phosphorus has been devised. The uptake of the impurity by protein (crystalline horse serum albumin) precipitated from a carrier-containing solution by trichloracetic acid was unaffected by the amount of protein used or the amount of carrier present over a wide range. The protein precipitate (see table) was separated by centrifugation from the supernatant fluid, which was then neutralized, more protein was added and the precipitation repeated. The second precipitate was found to contain less than one-thousandth of the radioactivity found in the first, whereas both precipitates contained essentially the same amount of phosphorus. The degree of contamination of the first precipitate by carrier-free phosphorus-32 is indicated by the ratio of its specific activity to that of the supernatant fluid (final column of table), which in the absence of impurity cannot be greater than 1. This experiment has been repeated using a tissue homogenate instead of horse serum albumin, with similar results. A high activity persisted in the first precipitate after ten washings in phosphate-containing trichloracetic acid, whereas the second precipitate gave only background counts after six washings.

The impurity extracted has the same decay-rate as phosphorus-32 and was thought to be radioactive orthophosphate adsorbed on to, or combined with, some extraneous particulate matter suspended in the carrier-free solution. An attempt was made to remove the impurity by filtration of carrier-containing material through a 0·25-μ 'Gradocol' membrane. This proved as effective as protein precipitation in removing the impurity, only background counts being obtained on a washed precipitate from filtered material, an aliquot of which before filtration had given a highly active washed precipitate. The impurity may also be removed by extracting the orthophosphate in *iso*butyl alcohol as a phosphomolybdate complex, when the impurity remains in the aqueous phase; after alkaline hydrolysis the impurity behaves like orthophosphate and is found in the alcoholic phase.

In experiments involving nucleoproteins in which nucleic acid turnover is measured by means of phosphorus-32, Schmidt and Thannhauser's method of fractionating the nucleic acids is frequently used. In this fractionation the radioactivity due to the impurity is removed from the protein during alkaline hydrolysis and appears as radioactive orthophosphate in the ribose nucleotides fraction, where it will give rise to gross errors. If reliable results are to be obtained from experiments involving proteins labelled with phosphorus-32, it is essential to ensure that the tracer solution is free from this impurity. Filtration through a 0·25-μ 'Gradocol' membrane after addition of carrier provides a reliable and simple method of doing this, while at the same time sterilizing the solution.

nert Gas Effects in the Oxidation of Hexane

ACCORDING to one scheme of hydrocarbon oxidaion[1], a link in the gaseous reaction chain at low temperatures is the formation of a peroxide radical:

$$R + O_2 \rightarrow RO_2^*, \qquad (1)$$

followed by:

$$RO_2^* + RH \rightarrow ROOH + R. \qquad (2)$$

The formation of RO_2 appears to have been first proposed for the low-temperature oxidation of gaseous higher alkanes by A. R. Ubbelohde[1]. Other authors have proposed variants which still involve (1) as a tep in the oxidation mechanisms.) Until it can be dissipated, for example, by collisions with other molecules, the energy of reaction must be stored for a short time in the RO_2^* radical. Various physical properties[2] of the hydrocarbon molecule may facilitate his storage of internal energy in reaction intermediates for much longer periods than would be possible in the combination of simpler groups, as in

$$H + O_2 \rightarrow HO_2. \qquad (3)$$

The energy stored can be utilized in a subsequent process in the reaction chain, such as reaction (2), provided that this reaction can occur before collisions n the gas phase favour the competing deactivation eaction:

$$RO_2^* + X' \rightarrow RO_2 + X^*, \qquad (4)$$

where X is any third body. A possibility of this kind has been put forward (ref. 1, p. 373) as one of he factors which explain the much greater influence on reaction velocity of increasing the concentration of hydrocarbon rather than the concentration of oxygen.

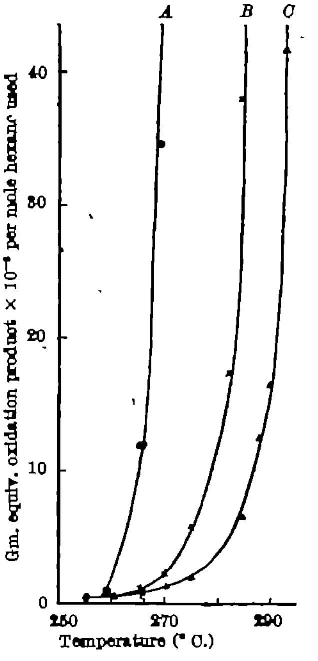

Fig. 1. Effect of diluents on hexane oxidations

With added hydrogen	2·87	1	4	4·26 H_2

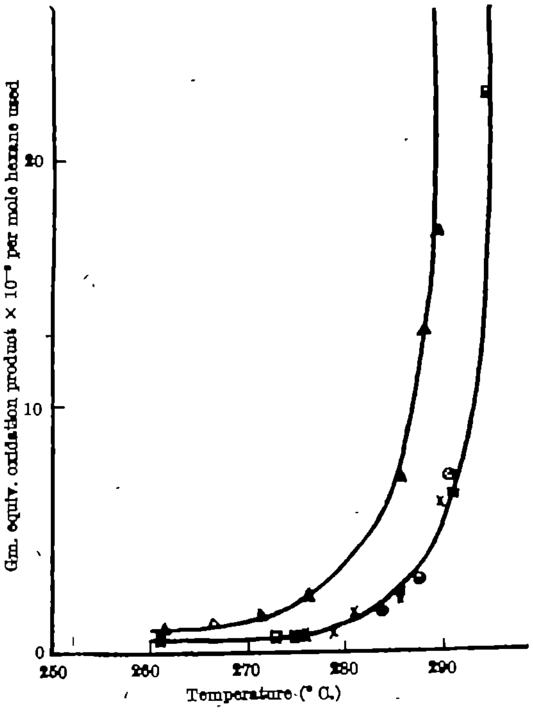

Fig. 2. Inhibition by mercury.
Mercury trough at 60° C, □; at 30° C., ×; at 0° C., ○

In the oxidation of gaseous acetaldehyde, it has recently been found[3] that dilution of the system by hydrogen leads to much more marked inhibition than dilution by nitrogen when introduced in comparable molecular proportions. Specific inhibition by hydrogen has now also been found for hexane oxidations using a flow system closely resembling that previously described[3]. In Fig. 1 the reaction temperature is plotted against the extent of oxidation, as measured by the total sum of peroxide, aldehyde and acid analysed in the condensible reaction products.

It seems likely that this specific inhibitory effect of hydrogen arises from energy-transfer processes in which collision with hydrogen is much more efficient in a reaction such as (4) than collision with nitrogen. The principle of microscopic reversibility indicates that if hydrogen is specially efficient in *removing* internal energy by collisions such as (4), it should also be much more efficient than nitrogen in other circumstances where the *supply* of internal energy by collisions involves the reverse of reaction (4). An elegant verification of the special efficiency of collisions with hydrogen for the transfer of internal energy is found in its influence on the thermal decomposition of ethers[4]. Similar evidence is obtained from ultrasonic measurements on vibrational specific heats[5].

We have also found that traces of mercury vapour slow down oxidation both in hexane + oxygen + nitrogen and in hexane + oxygen + (nitrogen + hydrogen) mixtures. For this purpose mercury was held (at the point A, see Fig. 1 in ref. 3) in a small trough heated electrically so that mercury could be vaporized into the gas stream at the desired temperature. For simplicity, only the inhibition observed in the presence of hydrogen as increased by the presence of mercury vapour is shown in Fig. 2. Since this added inhibition is not sensitive to the concentration of mercury, it may involve the action of mercury atoms as energy sinks in reaction (4). However, chemical inhibition such as could result from the removal of radicals by the formation of mercury derivatives in

$$R\cdot + \mathrm{Hg} \rightarrow R\mathrm{Hg}\cdot \qquad (5)$$

cannot yet be excluded on the basis of the evidence available.

An effect of hydrogen in suppressing the formation of cool flames in pentane[4] appears to be related to the present observations.

A New Method for the Detection of Amino-Acids, Peptides, Proteins and Other Buffering Substances on Paper

During the past few years, a large number of papers have appeared dealing with the quantitative determination of amino-acids in paper chromatograms *in situ* or after elution; but no simple satisfactory general method has yet been developed. Chemical reactions of the amino-acids on paper cannot easily be controlled, and results obtained from such reactions must be considered semi-quantitative. Elution of amino-acids after location of the spots in ultra-violet light seems to be the most promising method for quantitative estimation hitherto described. This method is based on the interaction between cellulose and amino-acids, which produces fluorescent substances[1]. The amino-acids take part only in the formation of intermediate compounds, from which they can be recovered quantitatively or almost quantitatively. The reactions are complicated and not fully understood[2].

Our method depends on a different principle. If a paper to which several spots of an amino-acid have been applied is sprayed with dilute acid, hydrolysis of the cellulose occurs only in the regions not occupied by the spots, for the amino-acid buffers the latter regions to a pH at which hydrolysis does not occur to a measurable extent. The only remaining requirement is a method of developing the part of the paper which has been hydrolysed. This has been accomplished as follows. The paper previously sprayed with acid is heated to 110–120° C. and then treated with glucose reagents. Orcinol gave the strongest contrast. By replacing hydrochloric acid by sulphuric acid we obtained still better results, depending on more complete hydrolysis and probably on the easier formation of ω-hydroxymethylfurfural from glucose. By the action of sulphuric acid, ω-hydroxymethylfurfural can, however, be converted to lævulinic and formic acids. To avoid this further destruction the orcinol was dissolved in the sulphuric acid solution. In this final method amino-acids applied to the pap as spots could be detected in amounts as small as 0·1

The most satisfactory treatment seems to be th following. The chromatogram is dried and the uniformly sprayed with a solution of 0·1 per cen orcinol in 96 per cent ethanol, made 0·004 *N* i sulphuric acid. (The paper will possibly contain considerable excess of acid with respect to the buffe substances, but the acid concentration can be varie within wide limits.) The paper is dried at 110–120° C and after about half an hour the colour is develope The spots appear white against a red-violet back ground. In ultra-violet light the spots were easil detectable.

Twenty acidic, neutral and basic amino-acid some peptides and proteins have been investigated and all gave easily detectable spots. Fig. 1 show leucine in different concentrations. Fig. 2 shows chromatogram developed with butanol–acetic acid.

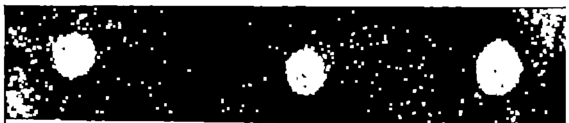

Fig. 1. Spots from left to right contain 5, 10 and 15 γ leucine respectively

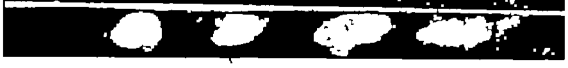

Fig. 2. Spots from left to right contain 5 γ glycine, 10 γ alanine, 15 γ tryptophane and 15 γ isoleucine

It should be noted also that minute amounts o citrate and borate buffers also gave well-defined spots

By eluting leucine, lysine and glutamic acid from paper and determining the amino-acids quantitatively according to the method of Moore and Stein[3], it wa found that the acids were not destroyed by orcino treatment. The results of these preliminary experi ments are given in the accompanying table. Th figures in the right-hand column refer to the orcinol treated paper, those in the left to the untreated paper The deviations are to a large extent due to variation in the ammonia content in the paper.

	Calc. (γ)	Found (γ)
Leucine	5·0	5·7
	10·0	9·5
	15·0	15·1
	20·0	19·9
Glutamic acid	10·0	9·0
	15·0	14·5
	20·0	21·2
Lysine	10·0	11·3
	20·0	19·7
	25·0	23·5

The experiments have shown that the metho described is suitable for the quantitative determina tion of amino-acids on paper chromatograms. Becaus of the greater specificity of the ninhydrin reaction we suggest that the following procedure should b adopted for amino-acid determinations. Two simultaneous chromatograms are run. One of them i developed with ninhydrin to simplify the exac localization of the amino-acids. After removal of th solvent, the other paper is developed with the orcinol reagent. The two chromatograms are then compared and the spots on the orcinol-treated paper corresponding to amino-acids are cut out, eluted and determined quantitatively according to some suitable method.

Peptides and proteins can be detected in minute amounts, although some hydrolysis may occur in the pots, which perhaps limits the method for preparative purposes.

The method should be of a great value also for the detection of other buffering substances which cannot be identified by more specific reactions. A possible generalization of our method would be to treat the paper with a substance the reaction of which is nhibited by the presence of spots of the compounds nder examination.

Separation of Alkaloids by Paper Chromatography

References to the separation of alkaloids on olumns by partition chromatography have been made by Catch *et al.*[1] and Partridge[2]. The theory and use of buffered columns have been previously described[3-5]. In the separation of the penicillins, buffered filter paper has been used[6], and the difficulty of obtaining absolute R_F values for such separations has been noted[7]. The water-insoluble alkaloids of ergot have been separated on unbuffered paper[8].

We have successfully used buffered filter paper for the separation of the strongly basic solanaceous alkaloids, and the feebly basic water-insoluble alkaloids of ergot.

In the case of solanaceous alkaloids, separation of atropine and hyoscine occur, and buffers of *p*H 5–9 were used. A weak solution of iodine in potassium odide and water was used to detect the alkaloid on the paper. $M/15$ buffer was found to be the most suitable strength, and of the buffers tried phosphate and citrate-phosphate gave the best results, while of the various solvents used *n*-butanol gave the nicest separations. The graphical representation of separations obtained at various *p*H values of a mixture of apoatropine, methyl nitroatropine, atropine and hyoscine is shown in Fig. 1. Similar separations can be made of brucine and strychnine; morphine, narcotine, cocaine and the quinine alkaloids give spots of varying R_F, using butanol and buffered paper.

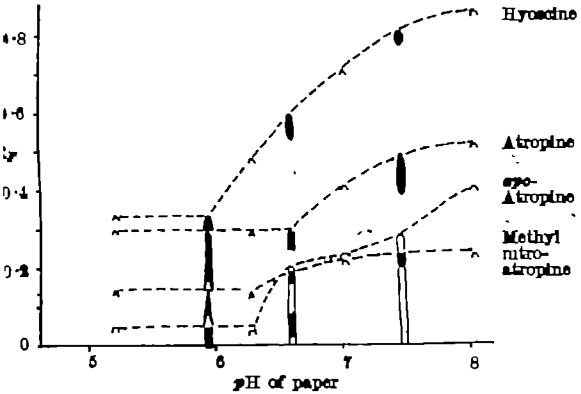

Fig. 1. Chromatograms of solanaceous alkaloids and related products

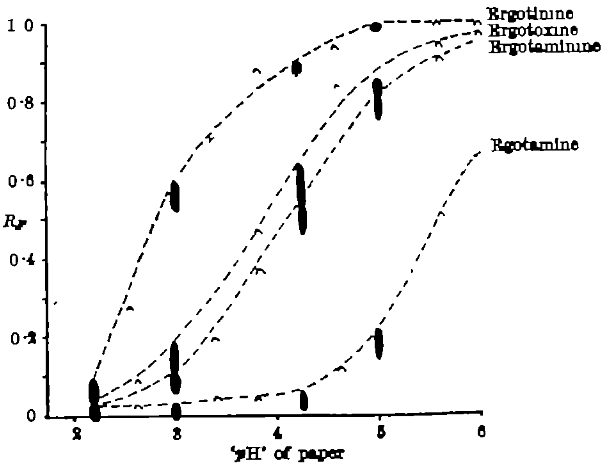

Fig. 2. Chromatograms of water-insoluble alkaloids of ergot

A similar method has been applied to the water-insoluble alkaloids of ergot, with the view of separating the physiologically inactive from the active alkaloids. By the use of buffered filter papers over the range '*p*H 2·2–6', varying degrees of separation of the water-insoluble alkaloids have been carried out. The most satisfactory solvent was diethyl ether saturated with water. In the accompanying graph (Fig. 2) the effect of the '*p*H' of the paper on the R_F value is shown, and the scope of the separations is obvious. With ether as solvent both lysergic and *iso*lysergic acid remain stationary. Ultra-violet light was used to detect the alkaloidal spots.

Quantitative estimations by elution of the alkaloid have not been satisfactory, recoveries varying from 75 to 88 per cent using 15–40 μgm. ergotoxine. These losses are being investigated. No resolution of ergotoxine into ergocristine, ergocornine or ergokryptine was observed in the systems used. Filter-paper chromatography is well suited to the qualitative analysis of the ergot alkaloids in view of the micro amounts used, but for quantitative work more promise is being shown by the use of buffered columns.

It is apparent that by the use of variations in *p*H and different solvents, very complex mixtures of alkaloids should be separable (provided that partition coefficients and/or the *p*K's differ). Thus, valuable information may be obtained for the 'scaling up' of comparable systems for macro separations, the very small amounts of material used in such preliminary investigation being a very desirable feature.

This work will be published in detail and an investigation is proceeding of the quantitative aspects of the separations described.

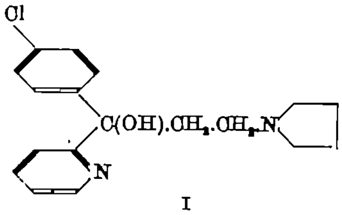
Geometrical Isomers in a Series of Antihistamines

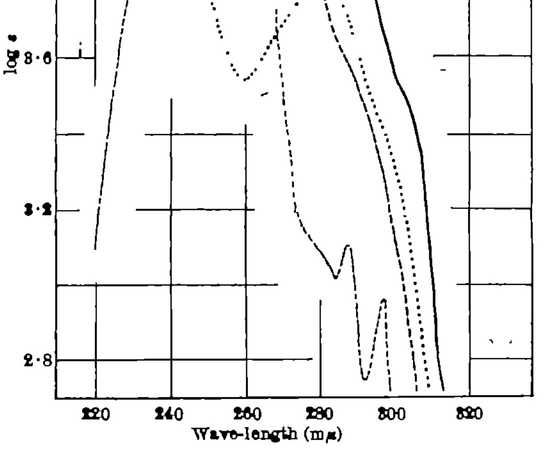
The dehydration of a series of 3-tertiaryamino-1-phenyl-1-α-pyridylpropan-1-ols (for example, I) by heating with 85 per cent sulphuric acid was described recently[1].



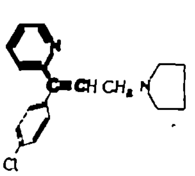
I

The allylamines so produced are of interest as antihistamines, in particular 1-p-chlorophenyl-1-α-pyridyl-3-pyrrolidinoprop-1-ene, also known as 405C49, which is among the most potent of known antihistamines. Further study of the preparation of this compound has revealed the presence of an isomeric base (496C50) in the product of dehydration. The isomers were separated by fractional crystallization of their oxalates (405C49 base, m.p. 61–62°; oxalate, m.p. 184° (decomp.); 496C50 base, oil; oxalate, m.p. 156–157° (decomp.)). The bases are apparently geometrical isomers, for each gave a high yield of the same ketone (p-chlorophenyl α-pyridyl ketone, m.p. 63°) on oxidation with chromic acid, and the same propylamine (n_D^{19}, 1·570; oxalate, m.p. 147°), when catalytically hydrogenated.

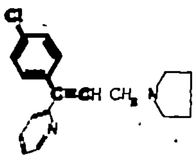
The ultra-violet absorption spectra of the isomers are remarkably distinctive, the one shown by 405C49 being almost identical with that of α-pyridylethylene, while that of 496C50 closely resembles that of p-chlorophenylethylene (see graph). We interpret these spectra as indicating that in 405C49, as in α-pyridy ethylene, the α-pyridyl and ethylenic groups a approximately co-planar, on the generally accepte assumption that this configuration is required f maximal electronic interaction of the two groups i which the characteristic light absorption is relate By the same reasoning, the p-chlorophenyl group 496C50, rather than the α-pyridyl group, is in th same plane as the ethylenic group. These configura tions are represented in formulæ II (405C49) an III (496C50), in which the approximately co-plana groups are heavily outlined. Chemical and physic evidence is being sought to determine the relativ configuration (cis- or trans-) of the aminomethylen moiety: it was not possible to make a decision o this point from examination of available molecul models.



Ultra-violet light absorption spectra. Ordinate, logarithm of molecular extinction coefficient, abscissa, wave-length in mμ ——, 405C49; . . , α-pyridylethylene; - - -, 496C50; – – –, p-chlorophenylethylene



II



III

Further, outstanding differences in chemical be haviour of the isomers have been observed. Fo example, 405C49 can be distilled unchanged unde reduced pressure, whereas 496C50 suffers decom position; 405C49 is unaffected by boiling aceti anhydride, whereas 496C50 is degraded to a mixtur of products of as yet undetermined constitution. W suggest that these differences in chemical reactivit may be attributed to the different resonance system preponderating in the isomers.

The dehydration of many related α-pyridyl carb inols has been re-investigated. In each case th results were similar to the example quoted above two isomers were formed, one being chemically stabl and exhibiting the α-pyridylethylene type of spectrum the other being relatively unstable and having spectrum similar to the corresponding substitute phenylethylene. Separation of the isomers wa usually effected by fractional crystallization of th oxalates or by chromatography, the progress of th separation being followed by measurements of th ultra-violet absorption spectra. The degradation o the unstable (phenylethylene type) isomer by aceti anhydride provided a convenient method for isolatin the stable (α-pyridylethylene type) isomer free fro the former.

The pharmacological properties of the isomer differ in an interesting manner. High and specifi antihistamine activity was shown only by the isomer having the α-pyridylethylene type of structure, th other isomer of each pair invariably being conside ably less active in this respect. In contrast, othe pharmacological activities were approximately of th same low order in both isomers. For exampl 405C49 is about eighty times more potent tha 496C50 when tested on histamine-induced spasm o guinea pig ileum; but the two compounds show onl minor differences in antagonism of acetylcholin spasm in guinea pig ileum, corneal anæsthetic activit in rabbits or toxicity in mice.

This series of isomers thus provides an illustratio of the selective influence of spatial configuration upo chemical and biological reactivity. We are followin up the more fundamental implications of these pre liminary results and intend to examine the application of these concepts to related compounds.

A more detailed description of the present work will be published elsewhere.

Oxygen Uptake of Nucleated and Non-nucleated Halves of *Amœba proteus*

THE removal of the nucleus causes a slow decrease of the ribonucleic acid content of the cytoplasm of *Amœba proteus*[1]. This indicates that the ribonucleoprotein particles (microsomes) subsist in the cytoplasm only in the presence of the nucleus. However, this nuclear control is not immediate, for the ribonucleic acid content of non-nucleated fragments drops significantly only after the fourth day following enucleation.

It appeared of interest to find out whether the oxygen uptake is under nuclear control; a rapid decrease of respiration after enucleation, as stated by Clark[2], might mean that respiratory enzymes, known to be predominantly bound to mitochondria, are dependent on the nucleus for the maintenance of their activity.

Measurements were made on nucleated and non-nucleated fragments of *Amœba proteus*, cut into two approximately equal parts with the aid of a glass needle, and kept fasting; a cylindrical Cartesian diver (gas volume approximately 7 c.mm.) was used. Preliminary experiments indicated that oxygen uptake is proportional to the number of amœbæ when 10–30 amœbæ per diver are studied. We found an average value of 0·3 × 10^{-4} c.mm./hr./whole amœba; this figure is almost one-fifth of that given by Clark[2] (1·4 × 10^{-3} c.mm.).

Sixty-nine measurements were performed, using 50–100 nucleated and non-nucleated halves; the time interval after enucleation varied from 1 to 10 days and respiration was studied during 4–5 hr. Duplicate experiments gave consistent results within ± 10 per cent.

As Holter and Zeuthen[3] have shown for intact amœbæ (*Chaos chaos*), the oxygen uptake decreases progressively during fasting and a similar phenomenon was found in the present experiments. But, as is shown in Table 1, the ratio between oxygen uptake of nucleated and non-nucleated fragments remains constant for at least nine days, and the uptake of the enucleated fragments 35–45 per cent that of the total.

Table 2

Day after sectioning	1	2	3	8	10
Ratio between tyrosine content of nucleated halves and of non-nucleated halves (N/E)	1·12 1·22	1·29 1·50	1·42	1·78 1·44	1 84

In order to check if the oxygen uptake is proportional to the protein content of the two fragments, we determined their tyrosine content according to the principle adopted by Andresen and Holter[4]; we followed detailed instructions kindly sent to us by Dr. Holter. The equal intensity of the Millon reaction in both types of fragments[1] justifies the choice of this amino-acid. As is shown in Table 2, results of these determinations expressed as the ratio between both fragments are reasonably of the same order as those found for oxygen uptake.

It can thus be concluded from the results that: (1) the oxygen uptake due to the nucleus of the amœba must be proportionally small; (2) the absence of nucleus does not prevent the prolonged maintenance of a normal level of oxidation. It then seems probable that the respiratory enzymes bound to mitochondria are largely independent of the nucleus for the maintenance of their activity.

It has recently been shown by Mazia and Hirshfeld[5] that phosphorus-32 uptake by amœbæ is strongly dependent on the presence of the nucleus: after twenty-four hours, enucleation results in the ratios nucleated : enucleated varying from 3·1 to 6·5. One is therefore led to believe that enucleation leads to a break in the normal coupling between oxidations and phosphorylations: the non-nucleated amœba would thus behave like cells treated with dinitrophenol, which interrupts synthesis by blocking the coupling between oxidation and phosphorylation. Work is now in progress to find out if the nucleus, and in particular the nucleolus, takes any part in the synthesis of the coenzymes necessary for this coupling. Our results, added to those of Mazia and Hirshfeld, give us a better understanding of the 'control' of syntheses by the nucleus.

Table 1

Day after sectioning	1	2	4	5	6	7	8	9	10

Ergothioneine in the Seminal Vesicle Secretion

PROTEIN-FREE extracts from the secretory fluid of the seminal vesicles exhibit a marked reducing property towards potassium permanganate and Folin's phosphotungstic reagent in the cold, and towards 2,6-dichlorophenol-indophenol in acid solution. Boar vesicular secretion, which is available in large quantities, was chosen as a convenient source for the isolation of the reducing material. In the course of purification, it was found that the reducing power went parallel with two other chemical properties of the boar vesicular secretion, namely, a strongly positive diazo reaction and the occurrence of organically bound sulphur which could be oxidized by bromine to inorganic sulphate. This suggested to us that the reducing substance may be the imidazole base ergothioneine (the betaine of thiolhistidine), first discovered by Tanret[1] in ergot, and later shown to occur in low concentrations in red blood corpuscles[2-4]. The application of certain analytical procedures for the determination of ergothioneine[5-7], both in the vesicular secretion and blood of boars, showed that the level of ergothioneine in the vesicular secretion averages 40 mgm. per cent as against 6 mgm. per cent in the blood.

The vesicular secretion collected from the seminal vesicles of four boars (1,300 ml.) was diluted with an equal volume of water and centrifuged; the supernatant was deproteinized with zinc hydroxide[8], the extract concentrated to 400 ml., precipitated with an equal volume of ethanol, the alcoholic filtrate concentrated to 200 ml., treated with 10 ml. 10 *N*-sulphuric acid, filtered again, and the water-clear and colourless solution precipitated with a 50 per cent solution of phosphotungstic acid. The precipitate was decomposed with barium hydroxide, and the solution, after removal of barium, was concentrated *in vacuo* to a syrupy consistency. On gradual addition of ethanol and cooling, crystallization set in, and after two days at 5° C., 480 mgm. of crystalline material was obtained. This gave two further reactions characteristic for ergothioneine, namely, a crystalline derivative with mercuric chloride, and trimethylamine on treatment with alkali. After two recrystallizations from 66 per cent ethanol and drying at 105° C., the substance was analysed—found: C, 47·14; H, 6·57; N, 18·24; S, 14·02. $C_9H_{15}N_3O_2S$ requires: C, 47·14; H, 6·59; N, 18·33; S, 13·98 per cent.

The correlation between the reducing power and ergothioneine content in the seminal fluid of other animals is being examined; but preliminary experiments indicate considerable variations in this respect between species.

This investigation was carried out on behalf of the Agricultural Research Council; one of us (E. L.) is indebted to the British Council for a scholarship, and to Prof. D. Keilin for hospitality in this Institute.

Inactivation of Adrenotropic Hormone (ACTH) by Plasma

The rapid disappearance from the blood of administered adrenotropic hormone (ACTH) has been demonstrated by Sayers *et al.*[1] using an infusion technique on human subjects, and Greenspan *et al.*[2], after intravenous injection into rats.

In view of the importance of these findings, we would like to report that we have observed the rapid inactivation of an adrenotropic hormone preparation during incubation with heparinized plasma from rats, rabbits and humans. Parallel incubation of the same preparation with the solvent containing an equivalent amount of heparin showed no measurable inactivation when assayed by the Sayers adrenal ascorbic acid depletion assay[3].

Sensitivity to Tuberculin

While a reasonable account can now be given of most stages of the mechanism of the urticarial type of skin response to injected antigens, the observed facts concerning the tuberculin or delayed type of reaction cannot yet be adequately explained. One of the main difficulties has been the failure to demonstrate circulating antibodies by the classical Prausnitz–Kuestner technique. However, Chase[1] showed that sensitivity to tuberculin could be passively transferred by the intra-peritoneal or intravenous injection of white cell concentrates from sensitized animals. More recently, this finding has been confirmed by Lawrence[2], who achieved passive transfer in the human by the intradermal injection of white cells from sensitized donors.

On the basis of tissue culture experiments certain workers, notably Rich and Lewis[3], Moen and Swift[4], had previously suggested a theory of 'tissue' or 'cellular' sensitivity to tuberculin, having demonstrated *in vitro* a cytotoxic action of tuberculin upon tissues from animals with experimentally induced tuberculosis. They found unequivocal evidence of the toxic action of tuberculin upon 'sensitized' wandering cells and observed that, while fibroblasts grew out in culture, their growth-rate was reduced and their cytological appearances altered. Aronson[5] and Raffel[6] demonstrated that bone marrow explants from sensitized animals were killed by tuberculin *in vitro*. No susceptibility of cellular elements to the antigen has been demonstrated *in vitro* when the urticarial or Arthus type of sensitivity has been investigated by tissue culture methods.

The development of a technique for growing explants of adult skin in a fluid medium by Medawar[7] has provided an opportunity for observing the effect of tuberculin upon skin *in vitro*. This technique permits a closer analogy to be drawn between the events following intradermal injection of tuberculin *in vivo*

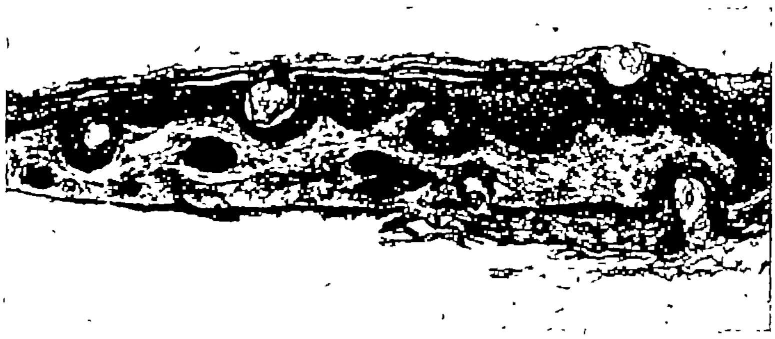

Fig. 1. A 2-day culture of guinea pig skin grown in medium containing purified protein derivative, 0·2 mgm./ml. Hæmatoxylin and eosin (× 100)

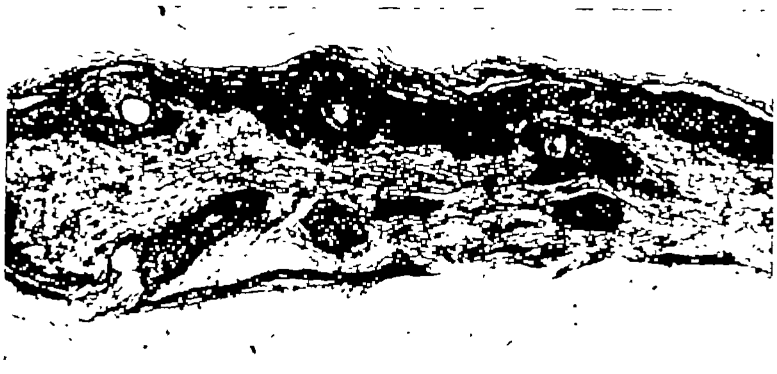

Fig. 2. A 2-day culture of skin from tuberculin-sensitive guinea pig grown in medium containing purified protein derivative, 0·2 mgm./ml. Hæmatoxylin and eosin (× 100)

and the submission of skin to various concentrations of tuberculin *in vitro* than the classical culture techniques using plasma jelly. The cells retain their normal growth pattern; epithelium from the epidermis migrates from the cut edges of the explant along the under surface of the dermis and is joined by epithelium spreading from the hair follicles. The dermis does not undergo any obvious change, but appears to retain its normal anatomical and cellular structure (Fig. 1).

In the experiments to be described a modification of the technique (suggested by Prof. Medawar) was used. Cultivation of skin explants 1–2 mm. square was carried out in 0·5 ml. of medium in 5-c.c. rubber-stoppered bottles in a gas phase of 60 per cent oxygen, 39 per cent nitrogen and 1 per cent carbon dioxide. The medium consisted of five parts serum (usually autologous), three parts Krebs–Ringer phosphate solution, one part 5 per cent glucose and 1 part streptomycin (500 units per ml.). The explants were lightly smeared with 'Vaseline' and floated on the surface of this medium. During cultivation the explants were rocked through 15° each way from the horizontal at about five times per minute.

The principle of the experiment was to compare the effects of tuberculin *in vitro* upon skin explants obtained from tuberculin-sensitive and normal guinea pigs. Sensitization was induced by the intradermal injection of heat-killed tubercle bacillus or by B.C.G. vaccination. The sensitized guinea pigs reacted to at least 1 : 1,000 old tuberculin and gave reactions from 1·5 to 2 cm. in diameter to 1 : 100 old tuberculin.

During cultivation for periods of up to three days, no differences could be detected in the amount and quality of growth between the sensitized and non-sensitized skin even in the presence of very high concentrations of tuberculin. In some instances the concentration of tuberculin (purified protein derivative, 0·2 mgm./ml.) was a hundred times that necessary to produce a tuberculin reaction *in vivo* (Fig. 2).

Proof of the presence of tuberculin in the medium after cultivation was afforded by the intradermal injection of 0·05 ml. of the medium into a sensitized animal in some of the experiments. Definite reactions were produced, although the diameter was somewhat smaller than that produced by the same concentration of fresh tuberculin.

The contrast between the non-reactivity to tuberculin *in vitro* and the tuberculin reaction *in vivo* is striking, and suggests that whatever the cause of the tuberculin reaction it is not associated with a direct cytotoxic effect of tuberculin upon sensitized skin. The evidence for the non-reactivity of the epithelium is weightier than that for the dermal cells, as the former is active in culture while the latter remain quiescent. The possibility cannot be excluded that biochemical changes may have occurred in the local tissue cells of the dermis which could not be detected by histological methods.

I wish to acknowledge the technical assistance of Mr. J. R. Cooper.

Inheritance of the Human Blood Group Antigen *Jk^a*

A NEW human blood group antigen has recently been reported[1]. The antibody is called anti-*Jk^a*; it divides Europeans into two phenotypes, *Jk*(*a*+) and *Jk*(*a*−). The frequency of the antigen is the same in London as in Boston, Mass.

	Jk(*a*+)	*Jk*(*a*−)	Total
Boston	146 77·25%	43 22·75%	189
London	154 76·62%	47 23·38%	201
Combined	300 76·92%	90 23 08%	390

Fifty-one families have been tested for the new groups. The antigen *Jk^a* is clearly controlled by a gene capable of expressing itself in single or double dose, for $Jk(a+)$ by $Jk(a+)$ matings can have $Jk(a-)$ children, and $Jk(a-)$ by $Jk(a-)$ matings do not have $Jk(a+)$ children. Statistical analysis of the families confirms that the inheritance depends on such a 'dominant' gene. The gene frequencies $Jk^a = 0{\cdot}5196$ and $Jk^b = 0{\cdot}4804$ can be derived from the tests on the 390 unrelated persons. From these frequencies can be calculated the proportion of children expected to be $Jk(a+)$ and $Jk(a-)$ from each of the three types of mating. Table 1 shows that the coincidence of the number of children in these categories, expected and observed, is very close.

Table 1. FIFTY-ONE FAMILIES WITH 124 CHILDREN TESTED FOR THE ANTIGEN Jk^a

Matings			Children				
				$Jk(a+)$		$Jk(a-)$	
Type	Exp.	Obs.	Total	Exp	Obs	Exp	Obs.
$Jk(a+)\times Jk(a+)$	30·2	31	80	71·6	72	8·4	8
$Jk(a+)\times Jk(a-)$	18·1	14	31	20·9	20	10·1	11
$Jk(a-)\times Jk(a-)$	2·7	6	13	0·0	0	13·0	13

Because of certain objections to this manner of analysis, Fisher[2] devised a more critical method for dealing with A_1A_2BO family data which can be easily adapted to the *Kidd* groups by treating $Jk(a+)$ as group B and $Jk(a-)$ as group O. Table 2 shows the good agreement between the observed families and those expected when the calculations are made in this way.

Table 2. ANALYSIS OF $Jk(a+)\times Jk(a+)$ AND $Jk(a+)\times Jk(a-)$ MATINGS

Class of mating	Class of family	Expected No. of families	Observed No. of families	χ^2	d f
$Jk(a+)\times Jk(a+)$	All children $Jk(a+)$	24·5	24	0·05	1
	Some children $Jk(a-)$	6·5	7		
$Jk(a+)\times Jk(a-)$	All children $Jk(a+)$	7·3	5	1·51	1
	Some children $Jk(a-)$	6·7	9		
				1·56 $p = 0{\cdot}42$	2

In the earlier communication[1] it was stated that χ^2 tests failed to show any relationship between the new antigen and the antigens of the *ABO*, *MNS*, *P*, *Rh*, *Lewis* or *Duffy* systems, or sex. The London results support this and also show no relationship to the antigens of the *Lutheran* or *Kell* systems, or to the ability to taste phenyl thiocarbamide.

Although all the 51 families were tested for the other blood groups, and most of them for phenyl thiocarbamide tasting, linkage information is so far rather scanty. The evidence, such as it is, is against the *Kidd* genes, Jk^a and Jk^b, being partially sex-linked or linked to the genes of the *ABO*, *MNS*, *Rh*, or *Kell* blood-group systems, or to the genes for phenyl thiocarbamide tasting.

The *Kidd* blood group is the tenth normal character in man, apart from sex, of which the manner of inheritance is known. The others are, in the order of their discovery: the *ABO*, the *MNS* and the *P* blood groups, the ability to taste phenyl thiocarbamide, the secretion of the *ABO* antigens in the saliva (with which is associated the *Lewis* blood group), and the *Rh*, the *Lutheran*, the *Kell* and the *Duffy* blood groups.

An Extension of Kosambi's Formula

KOSAMBI[1] proposed the formula

$$y = \tfrac{1}{2}\tanh 2x \qquad (1)$$

as an approximate representation of the relation between the genetical map-length x of a segment and y the amount of recombination over that segment. As corollaries, we have for adjacent segments x_1 and x_2:

$$y_{12} = 2y_1y_2y_{1+2} = 2y_1y_2\,\frac{y_1+y_2}{1+4y_1y_2}. \qquad (2)$$

I have indicated[2] the conditions under which these approximations are valid. If, in particular, the interference is represented by the intercept function $4u \exp -2u$ employed in previous work[2-4], then, for a segment near the (metrical) midpoint of a long arm, we obtain the relation

$$y = \tfrac{1}{2}\,(1 - \cos 2x.\exp -2x).$$

For segments less than 35 cM. in length this function differs from $\frac{1}{2}\tanh 2x$ to an inappreciable degree, the difference in the values of y as given by the two formulæ being only 8 parts in 302 when x is 35 cM. Thus, Kosambi's formula regarded as an approximation receives a simple theoretical justification, and it is seen that it is likely to apply in median segments.

In such a region an elegant representation is available if complex numbers are employed. Introducing the auxiliary quantity z, defined by

$$z = \tfrac{1}{2}\sin 2x \exp -2x,$$

and defining a *complex recombination fraction*, $y + iz$, written as w, we have the identities:

$$1 - 2w = \exp\{-2x(1+i)\},$$

and

$$w_1w_2 = \tfrac{1}{2}(w_1 + w_2 - w_{1+2}).$$

Therefore,

$$\begin{aligned} y_{12} &= \tfrac{1}{2}\,(y_1 + y_2 - y_{1+2}) \\ &= R\{\tfrac{1}{2}(w_1 + w_2 - w_{1+2})\} \\ &= R(w_1w_2) = R(w_{12}), \end{aligned}$$

if we write w_{12} for the product w_1w_2. It is seen that w satisfies the same relation as would be obeyed by y if there were no genetical interference. Thus for two adjacent segments the introduction of complex recombination fractions formally removes the effect of interference, making the 'complex coincidence' w_{12}/w_1w_2 equal to unity.

Also,

$$y_{12} = R(w_1w_2) = y_1y_2 - z_1z_2;$$

but since this relation approximates to that implied by (2), we obtain the useful approximate equation :

$$x_1x_2 \bumpeq (1-2y_1)(1-2y_2)/(1+4y_1y_2), \qquad (3)$$

which holds when x_1 and x_2 are sufficiently small. This last approximation, though deduced for adjacent intervals, clearly holds for non-adjacent ones also.

Hitherto there has been no extension of Kosambi's formula for simultaneous recombination to the case of non-adjacent intervals or to more than two adjacent intervals. This defect can now be remedied. Let y_1, y_2, y_3 ; y_{12}, y_{23}, y_{13} ; and y_{123} refer to adjacent intervals x_1, x_2 and x_3 located in a median region on a long arm. Then using the method of calculation previously indicated[2], we obtain :

$$y_{13} = y_1y_3 - x_1x_3 \exp -4x_2$$

and

$$y_{123} = R(w_1w_2w_3) + \tfrac{1}{2}x_1x_3(1 - \exp -4x_2). \qquad (4)$$

In the case of two adjacent intervals y_{12}, the frequency of simultaneous recombination is given by $R(w_1w_2)$. However, formula (4) shows that in the case of three such segments the analogous quantity $R(w_1w_2w_3)$ under-estimates y_{123}, as is otherwise obvious, because, relative to their lengths, the interaction between x_1 and x_3 is less than that between two adjacent segments.

Employing formulæ (1) and (3), we obtain as further approximations

$$y_{13} = y_1y_3\left\{1 - \frac{(1-2y_2)}{(1+2y_2)} \cdot \frac{(1-2y_1)(1-2y_3)}{(1+4y_1y_3)}\right\},$$

and

$$y_{123} = y_1y_{23} - y_2y_{13} + y_3y_{12}.$$

These formulæ have the merit of containing only the segmental recombination values y_1, y_2 and y_3. They constitute a theoretically satisfactory generalization of Kosambi's system. They enable the frequencies of the modes of gamete formation with as many as five linked loci to be expressed in terms of the segmental recombinations only.

Digestion of Alpha-Cellulose by Larvæ of *Anobium punctatum* De Geer

Parkin[1] demonstrated that the larval gut of the common house borer *Anobium punctatum* De Geer contained an enzyme or enzymes which produced reducing sugars from isolated oak α-cellulose *in vitro*. Falck[2] and Müller[3] concluded from chemical analyses of sound and digested wood that some α-cellulose was digested by the larvæ. The present investigation was undertaken to determine the amount of α-cellulose digested and its significance in the total diet of *Anobium punctatum*.

Of the four methods[1] available for investigation of the nutrition of wood-destroying insects, only the comparison of chemical analyses of sound and digested wood is applicable to this investigation. This method shows whether changes have occurred in the proportions of the constituents following digestion but cannot show the amounts digested unless an assumption is made that one component is unaffected by the digestive enzymes of the larvæ. Most workers have assumed that lignin is inert during digestion. If this is so, the amounts of other components digested are readily calculated from the lignin ratio of sound and digested wood.

Table 1. Lignin Content of Wood and Frass Samples

	Lignin content* : per cent w/w on equivalent oven-dry basis		Lignin ratio‡
	Wood	Frass	
A	31·00	38·46	0·806
B	30·79	37·01	0·832
C	30·76	37·91	0·811
D	30·13	37·30	0·808
E	33·67†	38·83	0·867
F	29·49	36·40	0·810
X	29·84	38·33	0·779

* Mean of two determinations ; standard error of mean lignin value 0·14 per cent. † Mean of four determinations : 33·48, 33·80, 33·72, 33·68 per cent. ‡ Standard error of lignin ratio 0·005.

Six blocks (*A*, *B*, *C*, *D*, *E*, *F*) of sapwood kahikatea (*Podocarpus dacrydioides* A. Rich.) each from a different tree and infested with *A. punctatum* were used as a source of material for analyses. A single block (*X*) of sapwood matai (*P. spicatus* R. Br.) was also used. Blocks were split, frass removed from larval tunnels, and the frass-free splints passed through a grinding mill to obtain the wood samples. The frass from each block was collected and sieved on a 100-mesh screen to free the fæcal pellets from chewings[4] of undigested wood. Wood and frass samples were extracted first with ether and then with acetone before analyses. Results are reported on a basis of extracted wood or frass. Lignin was determined by the 72 per cent w/w sulphuric acid method outlined by Purves[5]. Alpha-cellulose contents of the samples were obtained by the methods of Wise, Murphy and D'Addieco[6] and Wise and Ratliff[7], first isolating holocellulose by action of acidified sodium chlorite at 75°–80° C., and then extracting the holocellulose with 25 per cent w/w potassium hydroxide at room temperature, for three hours, under nitrogen.

Lignin content of each wood and frass sample, and their lignin ratio $\frac{\text{lignin content of wood}}{\text{lignin content of frass}}$ is listed in Table 1.

Since some wood has been destroyed by digestion, the α-cellulose values obtained by analyses of frass cannot be simply subtracted from the α-cellulose values of the matched wood sample to obtain the amount of α-cellulose digested. However, if no

Table 2. Cellulose in Wood and Frass Samples and the Calculated Digestibilities of Wood and Cellulose

	Percentage* cellulose in wood	Corrected frass cellulose†	Difference equals cellulose digested	Cellulose digested as percentage of cellulose in wood	Apparent total digestibility of wood‡	Discrepancy§

B	48·1	33·6	14·5	30·1	16·8	2·3
C	48·9	30·8	18·1	37·0	18·9	0·8
D	45·1	31·2	13·9	30·8	19·2	5·3
E	42·6	30·9	11·7	27·5	13·3	1·6
F	48·6	32·4	16·2	33·3	19·0	2·8
X	47·1	28·4	18·7	39·7	22·1	3·4

* By analyses of wood samples. † Cellulose in frass X lignin ratio. ‡ Apparent total digestibility of wood : (1-lignin ratio). § Wood digested other than cellulose (apparent total digestibility minus cellulose digested).

lignin has been digested, the lignin ratios in Table 1 are numerically equal to the weight of frass derived from a gram of ingested wood. Therefore, to obtain α-cellulose values of frass samples as a percentage of the wood ingested, the α-cellulose values obtained by analyses of frass samples have been multiplied by the lignin ratios in Table 1. The α-cellulose values of wood and the corrected α-cellulose values of frass, together with relevant calculations of digestibility of wood and α-cellulose, are given in Table 2.

From Table 2 it is apparent that differences in α-cellulose content of matched wood and frass samples account for all but a few per cent of the calculated total digestion. The wood digested, other than α-cellulose, must include some protein and probably starch and free sugars since an amylase is known to be present in the gut extracts[1].

Since only about one-third of the α-cellulose present in the wood is digested, it is interesting to speculate whether the amount of some substance or substances present in wood determines the extent to which α-cellulose can be utilized. Such material is unlikely to be part of the carbohydrate complex but could well be protein and/or accessory growth-factors, the significance of which in the nutrition of *A. punctatum* is as yet unknown.

Zinc Requirements of *Aspergillus niger*

Zinc is indispensable for the growth of all the higher plants, fungi, Actinomycetes and bacteria which have been examined, yet little is known of the role of zinc in metabolism[1,2]. Evidence has been presented recently, however, that phosphatase of *Penicillium chrysogenum* is a zinc-containing enzyme[3].

The zinc requirements of fungi have been determined largely from experiments in which glucose or sucrose has been used as the source of carbon. In the experiments described below the zinc requirements of *Aspergillus niger* were determined when the latter was grown on media involving a number of different carbon sources. The fungus was grown in surface culture in 100-ml. 'Hysil' or 'Pyrex' conical flasks in triplicate and harvested after 4 days incubation at 28° C. The basal medium contained ammonium nitrate, 0·3 per cent; dipotassium hydrogen phosphate, 0·05 per cent; magnesium sulphate, 0·05 per cent; iron, 0·5 p.p.m.; copper, 0·1 p.p.m.; and manganese, 0·05 p.p.m.

The media containing glucose, glycerol and peptone as carbon sources were purified free from zinc by extracting with chloroform solutions of diphenylthiocarbazone at pH 7·6[4], and those containing citric and gluconic acid by extracting with chloroform solutions of 8-hydroxyquinoline at pH 5·2[5]. Zinc was added as $ZnSO_4.7H_2O$ in graded amounts and growth response curves obtained.

Table 1 shows that for a given carbon source such as glucose there is a constant relationship between the amount of carbon used, the amount of growth made and the minimum amount of zinc required.

Table 1

Sole source of carbon (gm %)	Mycelial weight (gm.)	Minimum zinc requirement for optimum growth (p.p.m.)	Zinc requirement per gm. of mycelium (p.p.m.)
Glucose 0·25	0·018	0·015	0·83
Glucose 2·0	0·14	0·1	0·715
Glucose 5·0	0·38	0·3	0·79

Table 2 shows the relative zinc requirements for growth with different carbon sources.

Table 2

Sole source of carbon (gm. %)		Mycelial weight (gm.)	Minimum zinc requirement for optimum growth (p.p.m.)	Zinc requirement per gm. of mycelium (p.p.m.)
Glucose	2	0·14	0·1	0·715
Glycerol	5	0·069	0·05	0·725
Gluconic acid	5	0·15	0·015	0·10
Citric acid	5	0·074	<0·01	<0·18
Peptone	1	0·02	0·05	2·5

It will be seen that zinc is essential for growth on all the carbon sources; but considerably less is required for the metabolism of organic acids than for glucose or glycerol. It would appear, therefore, that zinc is chiefly required for some process involved in the metabolism of glucose or glycerol. It will also be seen that the zinc requirements for the utilization of glucose and glycerol, while being considerably greater than for the utilization of acids, are similar to each other. This may indicate that the utilization of glucose and glycerol involves the same metabolic pathway which would be expected if the Embden–Myerhof scheme exists in fungi, and that the zinc requirement occurs in that part of the metabolic path involved in the utilization of both substances; that is to say, after the formation of the triose phosphates in the Embden–Myerhof scheme.

The apparently high zinc requirement for the metabolism of peptone may be due largely to the formation of zinc complexes with the latter, thus diminishing the available concentration of zinc.

If the similar zinc requirements for the utilization of glucose and glycerol and for gluconic and citric acid do imply a similarity of metabolism, it may be that a study of minimum trace element requirements would be of value in determining whether two substances are metabolized by similar or different pathways.

A Case of Disturbed Metabolism in *Daphnia magna*

IN the first half of January this year, a marked decrease in the rate of reproduction was noticed in ultures of *Daphnia magna* that are being kept on a ood of different algæ (mainly *Scenedesmus* sp.) at 8–20° C. The algæ cultures are kept in large aquaria with fountain water with occasional addition of mall quantities of nitrates and phosphates. These ultures are aerated artificially and illuminated with normal light bulb.

Nothing else could be observed in the mother nimals except the lack of active ovaria in many of hem and a rather unusual amount of fat droplets. At the end of the same month the rate of reproduction had fallen to practically zero; the mortality ad also increased, and moulting took place only xceptionally. Closer observation of the animals evealed the fact that they were completely filled with fat droplets of a pink colour. These fat roplets formed a massive cover around the intestinal ract, from the first third of it down to the anus, while a great number of them could even be found t the base of the abdominal end claws. The thoracic ppendixes were filled with droplets of the same olour, and they were even detected around the ephridia. Of the ovaries nothing could be seen. While well-fed *Daphnia magna* (with large fat reerves) can be starved for many days, during which hey use up the fat, these abnormal animals would not consume their fat reserves during starvation, but died within about two days.

This irreversible fat-storage led to the idea that he *Daphnia* might be deficient in some substance, which either the algæ or the animals could not produce under the conditions offered to them. To nd out whether there was really a kind of deficiency nvolved or not, the following experiments were made.

The animals were split into five groups of equal umbers: (1) and (2) the animals were kept as controls nd continued to feed upon the mixture of algæ as efore; (3) besides algal food, the animals received nely dispersed egg-yolk for twelve hours every ay; (4) instead of egg-yolk a suspension of baker's east was given for twelve hours every day; (5) the nimals received the same food as before, but they were put twice a day under the light of a mercury arc Original-Hanau Analysen-Quarzlampe) for five mintes at a time, at a distance of 20 cm. from the arc, sing a filter.

Results. After the first day of treatment the nimals of groups (3) and (4) already showed increased itality. After the second day of treatment first gns of resumed ovarian activity were observed in oth groups. The control animals and those of group 5) showed no change in behaviour. After the third ay all animals of group (3) had moulted and most them carried summer-eggs. In group (4) most nimals had moulted and showed active ovaria. The ther animals continued to die and no moulting was bserved. After the fourth day some animals of roup (3) released young, and all animals were now arrying summer-eggs. *Daphnia* of group (4) showed eggs of the same type. Groups (1), (2) and (5) still howed no [illegible] of improvement. After this, treatment as stopped [illegible]d all animals were put back on normal ood. While the animals of groups (1), (2) and (5) till showed the same pink colour as before, those of roups (3) and (4) looked pale; their fat reserves ere of yellowish colour and reduced to normal size.

In the following days, some of the control animals and some of group (5) also showed some improvement—moulting and a slight egg-production.

Situation after three weeks. The animals of groups (3) and (4) have a high reproduction-rate (about 20 young per moult per animal); colour, yellowish-brown; fat storage small; about two-thirds of the animals have died since the beginning of the treatment. The control animals and those of group (5) have a poor reproduction (2–3 young per moult per animal); low vitality; pink colour, with abnormal large fat accumulations; of forty-five animals at the beginning of the experiment only three are still living.

It should be mentioned that during this period of abnormal behaviour the production of males or of sexual eggs was never noticed; this is true for the treated animals as well as for the untreated ones. The oxygen consumption, as measured by the Warburg technique, showed the following figures in c.mm. oxygen per 15 min. per mgm. dry weight: before and after metabolic disturbance, $M = 2\cdot97$ c.mm./15 min./mgm., $\varepsilon = \pm\ 0\cdot10$; during period of disturbed metabolism, $M = 5\cdot50$ c.mm./15 min./mgm., $\varepsilon = \pm\ 0\cdot16$.

These results support the idea that the abnormal metabolism described above has its origin in some food deficiency. Of course, the complexity of the egg-yolk and of the yeast does not allow the type of deficiency to be specified.

Heart-beat of the Hibernating Hedgehog

THE most characteristic feature of the physiology of hibernation is the changing of a homoiothermic mammal within certain limits into a poikilothermic animal. Thus, for example, the body temperature of the hedgehog may decrease during hibernation to about 2° C. When the animal wakes from hibernation, its body temperature rises in some hours from 2°–5° C. to 30°–35° C. again, and the animal returns to homoiothermy.

Owing to the low body temperature, the metabolism of the animal is greatly reduced during hibernation. This also has an effect on the heart function. The effect of hibernation on the physiology of the heart and the circulatory system has been but little investigated, however (cf., for example, Endres and collaborators[1], Ferdmann and Feinschmidt[2], and Suomalainen and Sarajas[3]).

With the aid of electrocardiograms we found that the mean normal heart-beat of the hedgehog (body-weight 420–920 gm.) is 188 per min. During hibernation (body-weight 420–770 gm., body temperature 6·2–7·7° C.) the mean heart-beat was 21 per min. The reason for this is primarily the lowering of the body temperature and strengthening of vagus tone, probably also increase in magnesium, decrease in potassium, and increase in carbon dioxide content of the blood during hibernation.

FORTHCOMING EVENTS

Wednesday, August 8—Wednesday, August 15

British Association for the Advancement of Science (at Edinburgh).—Annual Meeting.

Wednesday, August 8

At 8.15 p.m.—H.R.H. The Duke of Edinburgh, K.G., F.R.S.: "The British Contribution to Science and Technology in the Past Hundred Years" (Presidential Address).

Thursday, August 9

At 10 a.m.—Sir David Brunt, F.R.S.: "A Hundred Years of Meteorology (1851–1951)" (Presidential Address, Section A).

At 10 a.m.—Sir Cyril Hinshelwood, F.R.S.: "Chemistry at the Mid-Century" (Presidential Address, Section B).

At 10 a.m.—Dr. C. F. A. Pantin, F.R.S.: "Organic Design" (Presidential Address, Section D).

At 10 a.m.—Dr. O. J. R. Howarth: "The Centenary of Section E" (Presidential Address, Section E).

At 10 a.m.—Sir Henry Beresford-Peirse, Bart.: "British Forestry in the Last Century" (Chairman's Address, Section K*).

At 10 a.m.—Dr. E. M. Crowther: "Experimental Agriculture" (Presidential Address, Section M).

At 12 noon—Prof. C. A. Mace: "Psychology and the Laity" (Presidential Address, Section J).

At 12 noon—Prof. W. Brown, F.R.S.: "Mycology over a Century" (Presidential Address, Section K).

At 2.30 p.m.—Dr. D. A. Allan: "The Scottish Scene" (Presidential Address, Conference of Delegates of Corresponding Societies).

At 5.30 p.m.—Sir Edmund Whittaker, F.R.S.: "Eddington's Principle in the Philosophy of Science" (Eddington Memorial Lecture).

Friday, August 10

At 10 a.m.—Prof. R. G. Hawtrey: "The Nature of Profit" (Presidential Address, Section F)

At 10 a.m.—Sir Claude Gibb, F.R.S.: "Two Thousand Years of Engineering" (Presidential Address, Section G).

At 10 a.m.—Sir Cyril Fox: "The Study of Early Celtic Metalwork in Britain" (Presidential Address, Section H)

At 10 a.m.—Sir Hector Hetherington, K.B.E.: "Mid Century—Retrospect and Prospect" (Presidential Address, Section L)

At 5.30 p.m.—Prof. C. A. Coulson, F.R.S.: "The Place of Science in the Christian Faith" (arranged by the Research Scientists' Christian Fellowship).

At 8 p.m.—Prof. John Read, F.R.S.: "Alchemy and Alchemists".

Sunday, August 12

At 8 p.m.—The Very Rev. John Baillie: "Natural Science and the Spiritual Life."

Monday, August 13

At 10 a.m.—Prof. W. B. R. King, F.R.S.: "The Influence of Geology on Military Operations in North-West Europe" (Presidential Address, Section C).

At 10 a.m.—Prof. H. P. Gilding: "Physiology of the Capillaries" (Presidential Address, Section I).

At 7.30 p.m.—Session on "World Communications—The Impact of Speed" (Speakers will include Sir Edward Appleton, F.R.S., Sir Ben Lockspeiser, F.R.S., Dr. Edward Warner and Prof. P. Auger).

At 8 p.m.—Sir Edward Salisbury, F.R.S.: "The Contemplative Gardener."

APPOINTMENTS VACANT

Assistant (Scientific) in the Plant Protection Chemistry Section—The Secretary, East Malling Research Station, East Malling, Maidstone, Kent (August 11).

Head of the Engineering Department, and a Head of the Natural Science Department, of the Nigerian College of Arts, Science and Technology—The Secretary, Advisory Committee on Colonial Colleges of Arts, Science and Technology, 15 Victoria Street, London, S.W.1 (August 11).

Junior Cytogeneticist at the Commonwealth Potato Collection at Cambridge—The Secretary, Agricultural Research Council, 15 Regent Street, London, S.W.1 (August 11).

Physical Chemist on the Engineer's Staff—The Clerk to the Birmingham Tame and Rea District Drainage Board, 117 Colemore Row, Birmingham 3 (August 11).

Physicist to the Radiotherapy Department—The Secretary, Romford Group Hospital Management Committee, Oldchurch Hospital, Romford, Essex (August 11).

Assistant Lecturer or Lecturer in the Department of Botany, with a special interest in mycology—The Secretary, The University, Edmund Street, Birmingham 3 (August 13)

Lecturer in the Biochemistry Department, and an Assistant in Pathology in the Department of Animal Pathology, in the University Veterinary School—The Secretary of University Court, The University, Glasgow (August 15).

Lecturer (with a good honours degree in chemistry, research experience in physical chemistry, and prepared to teach the subject to B.Sc. Special standard) in Physical Chemistry, and an Assistant (with a degree in electrical engineering, or some equivalent qualification) in the Department of Electrical Engineering—The Clerk to the Governors, Woolwich Polytechnic, Woolwich, London, S.E.18 (August 15).

Professor and Head of the Department of Aircraft Design—The Registrar, College of Aeronautics, Cranfield, Bletchley, Bucks, endorsed 'Professor of Aircraft Design' (August 15).

Engineer I at a Ministry of Supply establishment in Berkshire, for design and development work on schemes for production of useful power from atomic energy—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting C.68/51A (August 18)

Engineer I by the Ministry of Supply in London, for capacit, assessment in aircraft manufacture and repair, advice on jigging tooling, repair methods, etc.—The Ministry of Labour and Nationa Service, Technical and Scientific Register (K), York House, Kingswa London, W.C.2, quoting C.411/51A (August 18).

Engineer/Chemist I by the Ministry of Supply in London, t be responsible for planning and production of respirators and anti-ga stores—The Ministry of Labour and National Service, Technical an Scientific Register (K), York House, Kingsway, London, W.C. quoting C.412/51A (August 18).

Lecturer in Electrical Engineering—The Registrar, King' College, Newcastle-upon-Tyne (August 18).

Research Studentship in the Department of Physics (in th field of U.H.F. radio research)—The Registrar, University Colleg Hull (August 18).

Assistant Registrar (woman, graduate, preferably in Science)—The Principal, Royal Holloway College, Englefield Green, Surre (August 20).

Studentships in Biophysics and in Medical Physics—Th House Governor, Royal Cancer Hospital, Fulham Road, Londo S.W.3 (August 20).

Junior Technical Assistant (Electrical) in the Engineerin Branch of the Production Department at London Headquarter —The National Coal Board, Establishments (Personnel), Hobar House, Grosvenor Place, London, S.W.1, quoting TT/362 (August 21

Principal Scientific Officer in the Intelligence Division o the Department of Scientific and Industrial Research—Th Secretary, Civil Service Commission, Scientific Branch, Trinida House, Old Burlington Street, London, W.1, quoting S.4051/5 (August 23).

Lecturer in Electrical Engineering, and a Statisticia (temporary) in the Department of Social and Industrial Medicine—The Registrar, The University, Sheffield (August 25).

Research Microbiologist in the domestic preservation of frui and vegetables section at Long Ashton Research Station—Th Registrar and Secretary, The University, Bristol (August 25).

Head of the Department of Mathematics (with the status o Reader), Makerere College (University College of East Africa)—Th Secretary, Inter-University Council for Higher Education in th Colonies, 1 Gordon Square, London, W.C.1 (August 31).

Senior Lecturer in Geography at Auckland Universit College, New Zealand—The Secretary, Association of Universitie of the British Commonwealth, 5 Gordon Square, London, W.C. (September 8).

Chair of Civil Engineering at the University of Adelaide—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Adelaide, September 30).

Agricultural Superintendent for extension work in Sierr Leone—The Director of Recruitment (Colonial Service), Coloni Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 quoting 27059/220.

Assistant Forecaster (with a university degree, preferably i science and specialized in meteorology) for the Basrah Port Directorate—The Crown Agents for the Colonies, 4 Millbank, Londo S.W.1, quoting M.26338.B

Assistant Lecturer in Pharmacognosy—The Secretary, Roya Technical College, Glasgow.

Assistant Research Manager in the Research and Development Branch, Windscale Works, Sellafield, Cumberland, to lead a applied research group investigating a wide range of problems associated with atomic energy development—The Ministry of Supply Division of Atomic Energy (Production), Risley, Warrington, Lanc

Cerealist by the Government of Iraq for the Directorat General of Agriculture, to improve the field and quality of cere crops (mainly barley, wheat, rice and millet) by selection and breedin —The Crown Agents for the Colonies, 4 Millbank, London, S.W.1 quoting M.18187.A.

Consultant Scientist (preferably with a degree in bacteriolog mycology or biochemistry) to advise the Ministry of Agriculture o the utilization and conservation of horticultural products grown i the Sudan—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Consultant Scientist 401'.

Demonstrator in Pharmaceutical Subjects—The Registrar Municipal College, Portsmouth.

Departmental Assistant (university graduate) in Agricultur at the School of Agriculture, Sutton Bonington—The Registrar, Th University, Nottingham.

Graduate (with a science degree, with physics or mathematics) fo operational research in the wool industry—The Secretary, Wo Industries Research Association, Torridon, Headingley, Leeds 6.

Insecticide Chemist in the West African Cacao Researc Institute—The Director of Recruitment, Colonial Office, Great Smit Street, London, S.W.1, quoting 27106/39.

Lecturer in Dairy Husbandry at Massey Agricultural Colleg Palmerston North, New Zealand—The Secretary, Association Universities of the British Commonwealth, 5 Gordon Square, Londo W.C.1.

Lecturer in Mathematics, and an Assistant Lecturer (Grade in the Department of Chemistry—The Clerk to the Governin Body, Battersea Polytechnic, Battersea, London, S.W.11.

Lecturer in Pure Mathematics or Applied Mathematics—Prof. W. G. Guthrie, Magee University College, Londonderry.

Male Assistant (Scientific) in the Hydraulics Researc Organization (Department of Scientific and Industrial Research Wallingford, to assist in hydrographic surveying of beaches an estuaries and also to assist in research into the effect of waves an currents on beaches—The Ministry of Labour and National Servic Wallingford, Berks, quoting No. 141.

Public Health Engineer in the Public Works Departmen Sierra Leone, to undertake anti-malarial drainage and other urba works—The Director of Recruitment (Colonial Service), Coloni Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 quoting 27322/201.

Senior Physicist to the Radiotherapy Department—Th Group Secretary, Wolverhampton Hospital Management Committe Royal Hospital, Wolverhampton.

SCIENCE AND THE LAYMAN

TWENTY years ago, at its centenary meeting in London in 1931, and again in returning to the scene of its first meeting in York in 1932, the British Association, both in the presidential addresses and in the proceedings of the meetings, looked back over the progress of science during the previous century, and in particular at the way it had assumed an increasingly important place in the life of the community. The annual meeting of the Association remains to-day, however, what it has been from its earliest years—the principal public forum in Great Britain for the review and general discussion of progress in all branches of science. The meeting in Edinburgh is thus appropriately regarded as part of the Festival of Britain, which aims at displaying the British contribution to civilization in the arts, in science, and in industrial design.

The Council of the Association decided at an early stage, accordingly, that it would be fitting for the programme of this 1951 meeting to include reviews of progress during the past century and, without substantial alteration to the normal character of the programme, some twenty reviews of progress in particular topics are being presented at this Edinburgh meeting. The presidential address of H.R.H. the Duke of Edinburgh, which is printed on p. 219 of this issue, reviews the British contribution to science and technology in the past hundred years, and what is worth noting here in the first place is that while the other addresses, like the presidential addresses at London and at York, are by men of science, the president disclaims any such title. At the outset he insists that he addresses the Association as a layman, and that his review is an endeavour to give an impression from outside of the march of science in the past hundred years and of the community's appreciation of the work of scientific men and women. But he is too modest in his estimate of his own claims to address the Association: his professional training in itself involves some elements of technology, if not of science; and it is manifest from this address that the President's appreciation and understanding of the outlook and achievements of science are in no way inferior to those of the Prince Consort, who occupied the presidential chair at Aberdeen in 1859. The Duke of Edinburgh in his address has ranged over a variety of subjects in science and technology, infinitely more complex than those displayed to his great-great-grandfather, and touched them with a discrimination and balance that few of the numerous addresses of a similar kind delivered during the present year have approached.

That may indeed be one justification for one who claims to be a layman addressing the Association from its presidential chair, and if, as the Duke of Edinburgh suggests, the very invitation demonstrated that science is not a magic circle, his address should help further to dispel the idea that science and technology are magic or mysterious activities apart from the ordinary activities of men and women and beyond their comprehension. In the modern world, such an impression is highly dangerous to the continuance of science, and, at a time when in Great Britain and in other countries the prosecution of scientific research depends more and more on public funds for support and less on private benefactions, it is of first-rate importance that the nature of scientific work should be clearly and widely understood.

The contribution of the Duke of Edinburgh's address to such a wider understanding is of real service to science. Besides this, in reviewing the implications of the British contribution to science in the past century and the lessons to be learnt from those achievements, he emphasizes some of the factors upon which continued advance depends, and indeed the economic prosperity of the British people. This part of his address is reminiscent of Sir Henry Tizard's presidential address at the Brighton meeting of the Association, from which indeed he quotes ; but even more than his review of the past, it bears the new President's distinctive imprint, and some of these warnings of the layman are not to be disregarded.

The Duke of Edinburgh recognizes to the full, for example, the value of co-operation and team-work in science and the way in which, with the growing complexity of research and the mounting cost of equipment, scientific and technical advance depends on such equipment. None the less, he points out that the basic discoveries which mark the great advances depend on the accident of individual genius, and it would be disastrous if no place were left for the individual investigator working in his own laboratory. Scientific discovery, in fact, only flourishes where it finds the right conditions, and of these the social climate is one of the most important. That is manifestly appreciated by the Duke of Edinburgh, though he obviously could not point to the risk of political climate discouraging initiative and enterprise. For example, it has been stated recently that the benefits of chemical industry, which has contributed so much to medical advances and the relief of suffering, might well cease to flow in the absence of competition and that new remedies might never be developed for the public benefit because of the disturbance involved to existing products. Only an alert and informed public opinion can prevent such dangers and ensure the social and political climate in which science and technology thrive.

The President is clearly aware of the vital importance of educating public opinion in all such matters, and if he spoke as a layman and amateur, it is well to be reminded that laymen and amateurs have still important contributions to make to science. Indeed, it may be questioned whether there can be any really wide understanding of what science is and how it works, save in so far as members of the community participate in some scientific activity at least in an amateur capacity. So long as they are based on a clear understanding of scientific principles and the method of science, the activities of the amateur photographer, the radio amateur, the bird watcher and many others all contribute to that end ; the great value of the field-work which is now receiving increasing attention is that it teaches students of a wide range of types how to pursue open-air activities which appeal to them in a scientific way.

Such work, quite apart from fresh observations to be added to the store of scientific knowledge, is of great value and is to be welcomed as assisting in turn the wider understanding of what science is. In its way such educational work is fully as important as the finding of a solution to the problem of higher technological education to which the Duke of Edinburgh specifically refers. Here, and elsewhere, his address indicates problems requiring urgent attention, and he need be in no doubt that the scientific men in Great Britain will find his address as stimulating as it is full of interest. But above all, it is to be welcomed as a fresh demonstration that the layman and amateur, using that word in its fine original sense, have a vital contribution to make in furthering mutual understanding between the man of science or technologist and the citizen ; an understanding which is essential both for the furtherance of the conditions in which creative scientific work can flourish and for the application of scientific knowledge for the benefit of mankind.

FIFTY YEARS OF PROGRESS IN SCIENCE

Scientific Thought in the Twentieth Century

An Authoritative Account of Fifty Years' Progress in Science. Edited by Prof. A. E. Heath. Pp. xv+387. (London : Watts and Co., Ltd., 1951.) 42s. net.

THIS book is a number of essays by thirteen authorities on their respective branches of science with an introduction by Prof. A. E. Heath, which is followed by a chapter on the philosophy of science by Prof. A. J. Ayer. The contributors are Prof. R. A. Fisher on statistics, Sir Harold Spencer Jones on astronomy, Prof. F. Llewellyn Jones on physics, Dr. Andrew Kent on chemistry, Prof. Duncan Leitch on geology, Prof. P. B. Medawar on zoology, Dr. E. B. Ford on genetics, Dr. J. C. Hawksley on general medicine, Dr. Alice Stewart on social medicine, Dr. Derek Richter on neurology, Sir Cyril Burt on psychology, Prof. Meyer Fortes on social anthropology and Donald G. Macrae on sociology. The editor and publishers are to be congratulated on bringing together the work of such a galaxy of men of science ; this in itself is indicative of the quality of the book.

Nevertheless, each author seems to have been restricted to a mere 7,000–9,000 words. Some of the writers have the gift of putting a quart, or often a gallon, into a pint pot, others clearly have felt themselves to be unduly hampered by lack of space ; but without exception an outline, albeit sketchy, of a half-century of progress in their respective subjects has been clearly and faithfully presented. It would appear unfair to single out a particular essay as outstanding, but Prof. R. A. Fisher's contribution seems to be particularly useful, in that he explains the nature of certain tools of research which he himself has helped to forge, and which have been so useful in the development of the biological and social sciences, described by some of the other contributors. Fisher sums up his position thus : "In the present century we have learnt (i) to conserve in its statistical reduction the scientific information latent in any body of observations, and (ii) to conduct experimental and observational inquiries so as to maximize the information obtained for a given expenditure".

It is strange that there is not a chapter on botany, especially as that on genetics only deals with the vegetable kingdom in the early paragraphs on Mendel. It is pleasing to find essays on social medicine, social anthropology and sociology in such a work as this; but as there is a separate chapter on neurology, why not one on bacteriology and another on physiology? Two only of the later chapters have bibliographies, though Sir Cyril Burt supplies useful footnotes instead. In view of the brevity of each essay, it would have been valuable had indications for further reading been supplied by every author.

The book jacket claims that the work is intended for the "general reader". The reviewer has some difficulty in picturing this general reader. Is he a reader with some scientific background or is he the intelligent 'man-in-the-street'? Have men of science yet been able to appreciate his mental processes? The problem arises when such splendid passages as the following occur in the work: "Other basic principles which have been suggested are Milne's *Principle of Impotence*, that one cannot tell where one is in the universe, and Bondi and Gold's *Perfect Principle*—that one cannot tell the cosmic time. Older principles, such as that of the conservation of energy, turn out to be trivial consequences of these principles"; or again, in another section, "T is a consistent estimate of a parameter θ if in large samples it converges in probability to the limit θ".

The painter Whistler said that his work was not to be valued at so much a square foot but in terms of the experience of a life-time. The same principle seems to apply to the present book, which costs two guineas. It is difficult not to recall the spacious days between the Wars when Mr. Gollancz was able to produce a larger and more comprehensive volume, with five or six times the amount of material of the present work, for the modest price of five shillings.

W. L. SUMNER

A PHILOSOPHER'S PHYSICS

Essays in Physics

By Viscount Samuel. Pp. vi+154. (Oxford: Basil Blackwell, 1951.) 7*s*. 6*d*. net.

AN 'event' has become a familiar word in philosophical literature, and for a variety of reasons. In the hands of the late Prof. A. N. Whitehead it achieved an almost æsthetic connotation among scholars. Now, the appearance of a set of essays by Lord Samuel is assuredly an event and, moreover, one to be pondered over and welcomed. Writing with the dignity and charm of an elder statesman, this slender volume of his resembles a subtle kind of tonic, to be taken with care, and perhaps not always without obtaining a prescription for it beforehand.

With justification, the author is scarcely enamoured of the tendency to confuse concepts of the mind with physical realities, and he complains that the present-day physics tends to blur the issue. The difficulty here is that Lord Samuel is an incorrigible optimist (a welcome enough quality these days), firm in his belief that there is in very truth a sharp boundary upon which to focus. It is conceivable, however, that, at any rate for some time to come, we may have to put up with a species of mental moratorium, not in a mood of despair, but as an honest facing of the facts. All of which suggests that some bold thinking along the lines of the late Edmund Husserl's "phenomenological bracketting" (or *epoché*) might provide a finger-post towards the solution of this particular dilemma, more especially in view of the radical *ding-an-sich* attitude inherent in it. Recollecting that Husserl started as a mathematician, and developed into an outstanding exponent of a presuppositionless philosophy, it seems by no means fantastic to propose a thorough search in that difficult terrain for some sort of a solution to this puzzle.

Lord Samuel lists three conclusions, two negative and one "more positive", which have an important bearing. First, the impossibility of measurement must not lead to the assumption of no causes. Secondly, the cause of any event cannot be a mental concept *per se*. (Incidentally, this seems but an echo down the centuries of what St. Thomas Aquinas thought of St. Anselm's views, or something very like it.) Thirdly, and indeed well said, is the need for speculation. Although it seems unlikely that any exception will be taken to these precepts, it is good to have them so aptly formulated.

Much of the remainder of the book is taken up with a discussion of certain lines of inquiry such as waves, particles, gravitation, and so on, followed by some observations upon quiescent energy. Lord Samuel will not expect to gather in a neat bundle of acceptances here; but his outlook is stimulating nevertheless. The collection ends with a letter from Prof. Albert Einstein, accompanied by an English translation; the German *verzicht* rendered as "resignation" is not very happy, but otherwise a sound piece of work. There is a slight misprint on p. 102 (7); but elsewhere the text is above reproach.

If two constructive hints are permissible, one is that Bohr's principle of complementarity might help to clarify some of the more obvious anomalies; the other is that in the concept of 'logical pressure' envisaged by the late Prof. E. A. Milne and exemplified in his epistemological approach to physics, probably lies the best hope of advance for which Lord Samuel so eloquently pleads.

CHEMISTRY OF PHENOLIC RESINS

Chemie der Phenolharze

Von Dr. K. Hultzsch. (Organische Chemie in Einzeldarstellungen, Band 3.) Pp. vi+193. (Berlin, Göttingen und Heidelberg: Springer-Verlag, 1950.) 19.60 D. marks.

THE technical importance of phenolic resins and their industrial exploitation have not been reflected in corresponding fundamental advances. Until the late 1930's, investigations on the basic structure of the resins were comparatively few and their results were often inconclusive, chiefly because of the complexity and difficulty of the problem. The position was markedly altered by the work in Sweden, Germany and Austria carried out by the schools of Von Euler, Hultzsch and Zinke, so that at the present time a considerable amount of relevant information has been accumulated. Whereas earlier investigators largely used the analytical method—that is to say, they attempted to break down resins into identifiable crystalline compounds—the Continental work has been mainly of a synthetic type involving identification of materials produced during resinification of such active compounds as phenolic alcohols.

Dr. K. Hultzsch's book is the first real attempt to correlate the available information. It constitutes an effort to review critically and comprehensively the considerable literature and diverse views accumulated over many years. Dr. Hultzsch has included a historical survey, an account of the condensation of phenols with aldehydes and other compounds on the basis of modern electronic ideas, a critical review of existing chemical knowledge, and chapters on the technology of a wide range of phenolic resins and on their testing. The book includes author and subject indexes, as well as 376 separate references to papers published up to 1948. Comparatively little of significance has been omitted, although a few papers of perhaps minor importance appear to have been overlooked. If the chemist has been catered for more fully than the technologist, the fact must be accounted a good fault, in view of the practical trend of so many plastics books produced hitherto.

Controversy will still continue on the mechanism of the phenol–formaldehyde reaction despite Dr. Hultzsch's attempt at clarification, while few will agree with his contention that little more now remains to be done on the chemistry of the subject. There is likely to be still greater disagreement with his emphasis on the quinone methide structure as an essential feature of the heat-hardening of phenolic resins; most workers are likely to take the view that the evidence is as yet insufficient. Nevertheless, the author deserves gratitude for stimulating curiosity in a difficult field of work, and his monograph can be recommended unhesitatingly as essential to all workers on polymers, particularly at this time, when the organic approach tends to be neglected in favour of the more popular physico-chemical method of attack.

Students and advanced research workers will equally welcome this publication, so long as they can cope with the none too easy style of German writing adopted by the author. N. J. L. Megson

AN ORNITHOLOGICAL PIONEER

Studies in Bird Migration

Being the Collected Papers of H. Chr. C. Mortensen, 1856–1921. Edited by Poul Jespersen and A. Vedel Tåning. (Published by Dansk Ornithologisk Forening.) Pp. 272. (Copenhagen: Ejnar Munksgaard, 1950.) 18 kr.

THE method of studying the movements and life-histories of birds by marking them with light metal rings on the feet is now used in many parts of the world and in some of them on a substantial scale; it has yielded results of great value and its possibilities are very far from exhausted. Bird-ringing of a cruder sort had been tried in a small way before; but it was not until 1899 that rings of various sizes with serial numbers and adequate addresses were introduced. This development was due to a Danish schoolmaster, Hans Christian Cornelius Mortensen (1856–1921), whose collected papers on the subject are now republished in an English translation. This suitably marks the jubilee of his pioneer effort; and it also makes more accessible the results of his work, which are still of intrinsic scientific value.

Not many more than five thousand birds were ringed under Mortensen's own scheme (as compared with about one million in the British Isles alone during the past forty years); but he had either the foresight or the good fortune to concentrate largely on interesting species yielding a remunerative percentage of recovery records. Thus, after an initial disappointing experience with ringing starlings on an inadequate scale, he obtained excellent results with the white stork, the heron and various species of ducks, gulls and birds-of-prey.

With the white stork, Mortensen was able to show that those bred in Denmark usually migrate south-eastwards across Europe, around the Levant and through East Africa to the extreme south—but sometimes south-westwards to North Africa. The more numerous records from German and Hungarian ringing have amplified the picture.

More than three hundred pintail caught during autumn migration at a duck-decoy on the island of Fanö, off the west coast of Jutland, were purchased, ringed and released. The recovery records, about 20 per cent of the number of birds ringed, showed that ducks of this species passing through Denmark in autumn come from a summer area which extends to northern Russia as far as the White Sea and the Arctic Ocean; and that in winter they reach the British Isles, Holland, France, Spain, Italy and the eastern side of the Adriatic Sea. This finding still stands for comparison with results obtained from subsequent ringing elsewhere, and it forms an essential part of the general picture that is being built up of the seasonal movements of the pintail.

Reconciled as one is to recovery-rates as low as a fraction of one per cent for small passerine species, one may well be envious of such figures as 28 recoveries out of 65 ringed in the case of the common buzzard, and 10 out of 13 in the case of the goshawk. These spectacular rewards for a relatively small effort showed the value of the method, although with the less remunerative species similar information can be acquired only gradually by organized ringing on a scale of which the pioneer possibly did not even dream. A. Landsborough Thomson

THEORY OF FUNCTIONS

Funktionentheorie

Von Prof. Constantin Carathéodory. (Lehrbücher und Monographien aus dem Gebiete der exakten Wissenschaften: Mathematische Reihe, Bande 8 und 9.) Band 1. Pp. 288. 36 Swiss francs. Band 2. Pp. 194. 24.50 Swiss francs. (Basel: Verlag Birkhäuser, 1950.)

THE title of this work is perhaps a little misleading, as suggesting a treatise on all the main aspects of the theory of functions; but it would be unreasonable to expect, even in two volumes, a full account of such an extensive subject, which can be approached in several different ways. Cauchy's method was based on integration around a contour, Riemann's on intuitive ideas derived from physics and geometry, and Weierstrass's on the power series.
